aqueous layer was separated and kept for pooling. The sediment-freon mixture was then extracted with 1 M sodium chloride, homogenized, centrifuged, and the aqueous part tested using the Dische reaction<sup>28</sup>. This procedure was repeated until no more DNA was extracted as shown by a negative Dische reaction. All the aqueous fractions giving a positive Dische reaction were then pooled and repeatedly treated with freon (2 volumes aqueous fraction and 1 volume of freon) until deproteinization was complete (that is, until no more precipitate appeared at the intersection). The final aqueous phase was then concentrated by dialysis under pressure in a 'Cellophane' bag against distilled water overnight at 5° C, followed by dialysis against 0.15 M NaCl for 2-3 days until the desired concentration of DNA was obtained (between 100 and 1,000 µg per ml.). The pH was adjusted with sodium hydroxide to 7.2. The final material was standardized by the Dische reaction against a standard from commercial thymus DNA obtained from the Mann Laboratories. This material was passed through a V ultrafilter of fritted glass before use. No attempt was made to separate any contaminating ribonucleic acid (RNA) or any polysaccharide which may be associated with this fraction. Since the starting material was a nuclear fraction, contamination with cytoplasmic RNA was believed to be minimal. Proteins and lipids were removed by freonization.

(5) DNA-sarcoma-*H* (DNA-*h*) was prepared in a similar way to DNA-*m*, except that the starting material was the nuclear fraction of a carcinoma of kidney obtained from a human case (MH-21).

In these experiments 48 new-born litters of AKR Swiss mice, divided into six groups, were used. Of these, five groups were treated with macromolecules, while the remaining group was given sterile 0.15 M sodium chloride. Treatment of the new-born mice (to be referred to as 'preconditioning') was started within the first 24 h of life. Male young were separated from females in each group, while the mother was left with the female offspring as an additional control. Each animal in Groups I-V received daily subcutaneous injections on the first, second and third days of life and weekly intraperitoneal injections for 17 weeks thereafter starting on the seventh day and ending on the 132nd day.

Group I received 20 injections of TPS-*m* (25 µg each), giving a total of 500 µg. Group II received 20 injections of NPS-*m* (25 µg each), giving a total of 500 µg. Group III received 20 injections of <sup>3</sup>H-TPS-*m* (0.83 µg each), giving a total of 17 µg, while Group IV was given 20 injections of a complex formed by <sup>3</sup>H-TPS-*m* and DNA-*h* (0.83 µg of <sup>3</sup>H-TPS-*m* and 2 µg of DNA-*h* per injection) with a total dose of 17 µg for <sup>3</sup>H-TPS-*m* and 40 µg for DNA-*h*. Group V received 20 injections of sterile 0.15 M sodium chloride.

Group VI received daily intraperitoneal injections of TPS-*m* of 100 µg each from the first to ninth day of life (a total of 700 µg). Between 10 and 30 days of age, DNA-*m* was given subcutaneously 100 µg every other day (a total of 900 µg), while between 39 and 80 days of age, both TPS-*m* and DNA-*m* were given every third day subcutaneously—100 µg of TPS-*m* on the left side and 100 µg of DNA-*m* on the right side (a total of 1,300 µg each).

All the litters were challenged with sarcoma 180 on the 135th day of age (3 days after the final injection). The tumour from the donor mouse was removed under sterile precautions into a sterile Petri dish. It was then minced with sterile scissors and transplanted in 2 × 2 mm amounts by the trocar method into the right axillary region. The mothers were also transplanted with sarcoma 180 at the same time. The donor mice were shipped from Jackson Laboratories in Bar Harbor, kept in our laboratories for a week, and then used for transplantation on the eleventh day of tumour age. The mice were observed daily for death, starting with the fifth day of tumour age after

Table 1. THE EFFECT OF PRECONDITIONING IN EARLY LIFE WITH MACROMOLECULES EXTRACTED FROM TUMOUR TISSUE ON SARCOMA 180 TRANSPLANTED MICE

Mean percentage inhibition was obtained by observing the difference between the treated groups and the untreated Group V expressed as a percentage of the untreated. A positive value indicates inhibition, while a negative value indicates enhancement.

Mean percentage improvement was calculated for cure rate, death rate and T/M (tumour weight to mouse weight) ratio. Mean tumour weight was excluded.

\* No therapy was given to Groups III and IV. † Figures in parentheses are percentages.

transplantation (that is, D-5). Tumour measurements were recorded every other day in terms of mean diameter of growth (MDG) in mm (the mean of two diameters—the longest diameter and another at right angles to it).

On the fifteenth day of tumour age (D-15), Groups I, II, V, and VI were treated with <sup>3</sup>H-TPS-m—30  $\lambda$  per 30 g mouse with an activity of 200  $\mu$ c. per ml. and a concentration of 2.72 mg per ml. All the males in each group were given one treatment intravenously, while the females were given one treatment orally. Ribonuclease (obtained from Mann Laboratories) was given subcutaneously, 250  $\mu$ g to each mouse, on the day of injection and on the following day. Groups III and IV were left untreated. To be considered a tumour take, the transplanted tumour should have an MDG of 6 mm or more. Similarly, to be considered as a cure it was necessary that a regression of a tumour should be obtained from an MDG of 6 mm or more to an MDG of less than 6 mm. Mice found dead were immediately autopsied. On the 83rd and 84th day of tumour age, the surviving mice were killed. All mice were studied for distribution of radioactivity in the tumour and the various organs. The results of these radioactive studies will be reported elsewhere.

Mean percentage inhibition was obtained for both tumour take and tumour growth by observing on the same day the difference in percentage take and in tumour growth between the treated groups and the untreated control mice in Group V expressed in terms of the percentage of untreated. A positive value indicates inhibition, while a negative value indicates enhancement. The figures reported in Table 1 correspond to the mean values for the three periods referred to in the Table, namely D-5, D-10 and D-14. Mean percentage improvement refers again to the difference in cure rate, death rate, and tumour weight over mouse weight (T/M) ratios between the treated and the control groups expressed in terms of the percentage of the control values. A positive value indicates improvement, while a negative value indicates harm as a result of the treatment used. T/M was used rather than tumour weight *per se* since it is believed to be a better indicator of tumour growth and toxicity.

### Induction of Immunity to Sarcoma 180 by the Use of Small Dosage of <sup>3</sup>H-TPS for the Conditioning of New-born Mice

It is apparent from Table 1 and Fig. 1 that the use of small dosage of <sup>3</sup>H-TPS-m (as in Group III) for the conditioning of new-born mice has induced a definite state of immunity against the transplantation of sarcoma 180 later in life. This increased immunity was apparent by D-10 where the percentage tumour take was 60 per cent for this group as compared with 83 per cent for Group IV and 89–100 per cent in the remaining groups. By D-14 all the other groups had 100 per cent take, with the exception of Group III, which maintained its initial

inhibition level at D-10 and which, in addition, showed a cure of the tumour in one of the mice. Thus only 5/10 (50 per cent) of the animals had tumours at this time.

The mean percentage inhibition of tumour take for D-5, D-10 and D-14 as shown in Table 1 was +47. Similarly, the mean percentage inhibition for D-5, D-10 and D-14 showed a high value of +58. By D-21 two other animals in this group became cured, leaving only 3/10 of the animals with tumours. This situation remained until D-83, the day of killing. This meant that 7/10 (70 per cent) of the mice in whom small dosage of <sup>3</sup>H-TPS-m was used in early life have achieved protection against tumour challenge—with either no tumour developing at all or with subsequent regression of their tumours. There were no deaths in this group and the T/M ratio was 0.07 (the second lowest), while the mean percentage inhibition was +86 (the second highest).

It is to be emphasized that this group did not receive any therapy after tumour transplantation. It is also to be emphasized that the designation of the dose used in this group as 'small' is relative to the larger dose used in other groups. The work of Siskind *et al.* points to the ease with which immunity can be induced in new-born mice with pneumococcal polysaccharide antigens. It is likely that immunity in new-born mice could be induced with much smaller doses of TPS given only once on the day of birth.

Fig. 1. The role of tritiated tumour polysaccharide (<sup>3</sup>H-TPS) in the prevention and treatment of sarcoma 180 of mice. Groups I (TPS-m), II (NPS-m), V (NaCl) and VI (DNA-m and TPS-m) were treated with <sup>3</sup>H-TPS-m. Groups III (<sup>3</sup>H-TPS-m) and IV (<sup>3</sup>H-TPS-m + DNA-h) were immunized but not treated.

It was not possible to determine from these experiments the exact role of the tritium labelling of TPS in this beneficial host response. Tritiation does not affect the antigenicity of TPS<sup>16</sup>. Although it may be possible to explain the improved host response in this group on a purely immunological basis, it appears that tritium labelling is of additional benefit to the host. The results of therapy with <sup>3</sup>H-TPS-*m* and radioactive isotope determinations (to be published elsewhere) suggest that both factors, the immunological and the radiological, are responsible for this phenomenon.

The finding that <sup>3</sup>H-TPS-*m* in small doses is capable of inducing immunity in mice which later received sarcoma 180 indicates that TPS is the antigen concerned with immunity to tumour transplantation. It is, therefore, the key antigen which is expected to bear a causal relationship to tumours and tumour induction, and justifies the basic role assigned to it in the immunological unitarian concept referred to earlier. Moreover, the protection of 70 per cent of the mice in this group represents one way for the successful immunization against the transplantation of sarcoma 180 in mice.

#### Interference with the Immunizing Capacity of Small Dosage of TPS-*m* by DNA-*h*

Of great interest is the behaviour of Group IV, which indicates that DNA-*h* can interfere with the immunizing capacity of small doses of TPS-*m* (as demonstrated earlier in Group III). The mice in Group IV, preconditioned with a complex formed *in vitro* by TPS-*m* and DNA-*h*, manifested a 67 per cent tumour take on D-5 (compared with 40 per cent for Group III); 83 per cent on D-10 (compared with 60 per cent for Group III); and a 100 per cent on D-14 (compared with 50 per cent for Group III). By D-21, while Group III had a 70 per cent cure rate, this group had only one-sixth (that is, 17 per cent) cure rate. On D-33 only three-sixths (50 per cent) were alive as compared with 10/10 (100 per cent) in Group III.

The mean percentage inhibition of tumour take was 4.7 times less, and that for tumour growth 5.3 times less, than the comparable values for Group III. The cure rate was decreased from 70 per cent in Group III to 50 per cent in Group IV, while the death rate rose from 0 in Group III to 50 per cent in Group IV.

Earlier it was shown that a common antigenicity exists between TPS obtained from sarcoma 180 and that obtained from human tumours<sup>16</sup>. It is, therefore, not surprising to find that an interaction has taken place between TPS-*m* from the mouse and human DNA-*h*. This further indicates the specific interaction between TPS and DNA as reported earlier<sup>16</sup>. It appears that as a result of the complexing of TPS and DNA, the immunologically reactive sites on the TPS molecule are only partially available for the stimulation of the immune response. In addition, antibodies to DNA and to DNA-TPS complexes may be formed which may compete with anti-TPS antibodies and interfere with their beneficial effect. The result is a state of only partial immunity associated with a higher death rate.

This interaction between TPS and DNA is believed to be of basic significance in host-tumour relationships. In this connexion it is of interest to refer to my earlier finding<sup>29</sup> that the uptake of <sup>3</sup>H-TPS by cancer tissue was found to be blocked by commercial DNA, RNA and by NPS but increased with pretreatment with TPS. Recently, Mannick<sup>30</sup> reported an inhibition of the homograft immune response by incubation of immune lymph node cells with RNA extracted from lymph nodes of the homograft donor or from lymph nodes of an indifferent rabbit. Since transplantation antigens are believed also to be polysaccharide in nature<sup>21,22</sup>, this interaction between nucleic acids and polysaccharides is further emphasized. It is pertinent to refer again to the investigations of Paleczuk *et al.*<sup>31</sup> and of Plescia *et al.*<sup>17</sup> concerning DNA-

associated antigens. These workers found complexes between nucleic acid and polysaccharide revealed by heat in *Brucella abortus* and also in the Ehrlich-Lettre mouse tumour cells. These antigens, which were found to be polysaccharide in nature, were only revealed after heating DNA-rich preparations to 100° for 10 min. It is of interest to note that in our original preparation of TPS<sup>12</sup> heat at 100° was used for 30 min. It is not unlikely that this interference by DNA in the antigenicity of TPS may explain in part some negative results in which investigators were unable to detect antigens in whole homogenates of tumour tissue.

#### Induction of Susceptibility to Sarcoma 180 by the Use of Large Dosage of TPS-*m*

The mice in Group I receiving 500 µg of TPS-*m* in early life did not manifest an increased immunity, but rather an increased susceptibility to transplantation of sarcoma 180 in later life when compared with the control group receiving 0.15 M sodium chloride (that is, Group V). This trend was less apparent in the early part of the experiment before treatment was started, but became well established after therapy with <sup>3</sup>H-TPS-*m*. Thus by D-5 the percentage tumour take was similar in the two groups, while the MDG was greater for Group V. By D-10, the percentage tumour take was 89 per cent for Group I as compared with 100 per cent for Group V, while the MDG was now slightly greater for Group I than for Group V. The mean percentage inhibition before therapy was +3 and +2 for tumour take and tumour growth respectively, while the mean tumour inhibition became -73 after therapy. The cure rate was 22 per cent (compared with 33 per cent in Group V), the death rate was 56 per cent (compared with 22 per cent in Group V) and the *T/M* ratio was 0.17 (compared with 0.13 in Group V).

This unresponsiveness to sarcoma 180 induced by the use of large dosage of TPS-*m* seems to be a specific phenomenon, since NPS-*m* given at the same dose-level (that is, 500 µg as in Group II) did not give rise to it. In this latter group (Group II), there was a mean percentage inhibition of +23 for tumour take and +17 for tumour growth, while the mean percentage improvement was +25. It was of interest to note that the cure rate was 50 per cent as compared with 22 per cent for Group I and 33 per cent for Group V. The death rate for Group II was 25 per cent as compared with 56 per cent for Group I and 22 per cent for Group V.

The finding that small doses of TPS-*m* can induce immunity, while large doses can induce susceptibility to sarcoma 180, may explain the paradoxical phenomenon of increased immunity as described by Barrett<sup>32</sup> and of enhancement as described by Kaliss<sup>33</sup> in response to immunization with tumour tissue. It is of interest to note the fate of one animal in this group, which was not included in this investigation since it died before tumour transplantation but which manifested a unique phenomenon. This was a male injected with large doses of TPS-*m* (25 µg per injection with a total dose of 475 µg). Three days after the nineteenth injection and two days before receiving the final injection, the mouse experienced breathing difficulty and paralysis of the hind legs, while lumps became apparent under the jaw, at the back of the neck and in the thigh regions. The mouse died the next day. At autopsy, 11 bean-shaped glands were found, the largest measuring 13 × 8 × 8 mm and the smallest measuring 2 × 1 × 1 mm—four in the cervical region, five in the axillary region and two in the inguinal region. Microscopic examination as reported by Dr. C. F. Varga<sup>34</sup> of the Pathology Department, Muhlenberg Hospital, revealed that "the tissue is composed of lymphocytes heavily infiltrated by plasma cells and having very little underlying stroma. There was no evidence of malignant tumour and the picture was believed to be compatible with lymphocytic and plasmocytic hyperplasia". Baruah<sup>34,35</sup>

had shown that the host animal (rat or mouse) reacts to a progressively growing transplanted tumour by developing a characteristic plasma-cellular reaction in the draining lymph node and spleen and that plasma cells are involved in the production of antibodies against the tumour. This plasma response was believed to be the basis for the heightened 'adoptive immunity' described by Mitchison<sup>36</sup> for mouse lymphosarcoma and confirmed by Billingham *et al.*<sup>37</sup> using skin homografts. The marked plasma cellular reaction in a mouse receiving TPS provides another link in the chain of evidence pointing to TPS as the antigen concerned with the host response against tumours.

#### Response of Mice with Sarcoma 180 to Therapy with <sup>3</sup>H-TPS-*m*

The response of mice in Groups I, II, V, VI and that of the mothers to the one treatment given on the D-15 tumour age with 30  $\lambda$  per 30 g mouse (containing 0.82  $\mu$ g of <sup>3</sup>H-TPS with an activity of 60  $\mu$ c.) is recorded in Table 1 and Fig. 1. The most successful results were shown by Group VI, in which unresponsiveness to both TPS-*m* and DNA-*m* was induced. In this group 90 per cent were cured, none died by D-83 and the mean tumour weight was 0.87 g, with a *T/M* ratio of 0.02—the lowest among all groups. The mean percentage improvement was +119.

The next best response was that of Group II, in which unresponsiveness was induced to NPS-*m*. In this group 50 per cent became cured and 25 per cent died. The mean tumour weight was 2.06 g and the *T/M* ratio was 0.08. The mean percentage improvement was +25 per cent. The control group (Group V) receiving only 0.15 M sodium chloride in early life had a 33 per cent cure in response to treatment with <sup>3</sup>H-TPS-*m*; 22 per cent death rate; a mean tumour weight of 4.20 g, and a *T/M* ratio of 0.13.

Among the litters, the group with the poorest clinical response to therapy was Group I, in which unresponsiveness to TPS-*m* was induced in early life. In this group the cure rate was only 22 per cent, the death rate 56 per cent, the mean tumour weight 4.26 g, the *T/M* ratio 0.17, and the mean percentage improvement, -73. The response of the mothers to therapy was very poor—a 20 per cent cure rate, 80 per cent death rate, a mean tumour weight of 4.62 g, a *T/M* ratio of 0.14 and a mean percentage improvement of -104. Of great interest is the finding that the only cure in this group was the mother of Group III—the group which received a small dose of <sup>3</sup>H-TPS-*m* in early life and in which a 70 per cent cure rate was observed without any treatment. This may represent a form of repeated immunization of the mother by minute doses of <sup>3</sup>H-TPS-*m*, the result of licking offspring, or of contamination from the urine of the offspring. The other mothers died as follows: *M*-VI on D-37; *M*-I on D-27; *M*-IV on D-23; and *M*-V on D-20.

The remarkable response of Group VI to therapy with <sup>3</sup>H-TPS-*m* will be analysed more fully elsewhere when the distribution of radioactivity in various tissues will be reported. In this article two possible explanations of this phenomenon of cure will be briefly referred to. First, it may be explained on the basis of increased and selective uptake by tumour cells of <sup>3</sup>H-TPS-*m* as compared with normal cells. This could destroy the tumour cells—the result of damage by  $\beta$ -rays of tritium—without affecting the neighbouring normal cells. This was the original aim of these investigations. This possibility, however, seems to be less important, since the uptake of <sup>3</sup>H-TPS-*m* by tumour cells does not seem to correlate with cure, while the uptake of <sup>3</sup>H-TPS-*m* by lymph glands has a more meaningful correlation.

Secondly, this phenomenon may be explained on the basis of what may be called 'reverse tolerance', where the state of immunological unresponsiveness becomes reversed

to a state of responsiveness and immunity in the host as a result of a direct effect on the reticulo-endothelial lymphocyte system. On the macromolecular level, this could be explained as follows.

While a poor response to therapy was obtained in Group I made unresponsive to TPS-*m* in early life, a remarkable response to therapy was observed in Group VI made unresponsive to both TPS-*m* and DNA-*m*. The difference therefore seems related to the host immune response to DNA. In the presence of such an immune response to DNA (as in Group I), antibodies to DNA would be expected to form and to combine with any reactive sites on the abnormal DNA molecules—a situation which would interfere with the uptake of <sup>3</sup>H-TPS-*m* by DNA-*m*. In this connexion it is interesting to note my earlier finding of antibodies to DNA in cancer homogenates<sup>38</sup>. In the absence of such an immune response, and in the presence of a state of unresponsiveness to DNA (as occurs in Group VI), the reactive sites on the DNA molecules will remain free and available for interaction with <sup>3</sup>H-TPS-*m*. The result of such an interaction between <sup>3</sup>H-TPS-*m* and DNA-*m* may well transform an abnormal DNA into a normal DNA as the result of the energy liberated from tritium. Should this happen in a lymph gland (made unresponsive to TPS and therefore unable to form protective antibodies against TPS), such a reverse transformation of abnormal DNA to normal DNA may well mean a reactivation of protective antibody formation and may explain the cure observed in this group.

It has been shown earlier using the Schultz-Dale technique and cutaneous hypersensitivity<sup>16</sup> that such an interaction between TPS and DNA can occur. It is in fact evident from this investigation, as shown by Group III, in which interference with the immunizing effect of small dosage of TPS was manifested by DNA. It is to be emphasized that in Group VI, TPS-*m* and DNA-*m* were not complexed before injection as was done in Group III. In fact, TPS-*m* injections were made on the left side of the animal, while DNA-*m* injections were made on the right side. It is also worth noting the finding by Siskind *et al.*<sup>7</sup> that between the day of birth and one month of age mice do not appear to differ with respect to ease of induction of unresponsiveness. The fact that the mice in Group VI received TPS for the first nine days of life and DNA from day 10 to day 30 of age should not make much difference so far as the induction of unresponsiveness is concerned.

In conclusion, it should be emphasized that the results reported in this investigation are of theoretical and practical significance in cancer immunology. Theoretically, these results provide confirming evidence for the immunological unitarian concept of cancer as postulated earlier<sup>16,18</sup>, in which TPS has been assigned a key role in the explanation of immunity and susceptibility to cancer. This concept is to be published in book form shortly<sup>19</sup>. Also this novel interaction between TPS and DNA, which has been described earlier<sup>16</sup> and which we believe to be of basic significance in biology, is further confirmed.

From a practical point of view, these results indicate clearly the significance of TPS in relation to immunity and susceptibility to cancer. Thus, while mice given small doses of <sup>3</sup>H-TPS-*m* in early life manifested a definite immune response against transplanted sarcoma 180, mice given large doses of TPS-*m* became immunoparalysed and exhibited an increased susceptibility to the disease as well as an increased death rate. The utilization of small doses of TPS-*m* as a vaccine to stimulate the immune response against tumours in man thus becomes a possibility. Furthermore, the successful treatment of tumour-bearing mice with <sup>3</sup>H-TPS-*m* when the host is properly conditioned may afford a new and promising approach to the therapy of cancer in man.

This work was done while I was director of research at the Muhlenberg Hospital, Plainfield, New Jersey. ]

## FINE STRUCTURE OF A VESICULATED RETICULUM IN THE LIGHT ORGAN OF THE GLOW-WORM, *Lampyrus noctiluca*

By V.-C. BARBER and P. N. DILLY

Department of Anatomy, University College, Gower Street, London, W.C.1

AND

C. W. T. PILCHER

Department of Neuropathology, National Hospital for Nervous Diseases, Queen Square, London, W.C.1

RECENTLY a histochemical and electron microscopical study of the light organ of the glow-worm (*Lampyrus noctiluca*) was undertaken<sup>1,2</sup>. A vesiculated reticulum, not previously described, was found to be present in the cells of the photocyte layer.

Previous electron microscopical studies of the light organ of fire-flies have given much morphological information<sup>3,4</sup>. Smith<sup>5</sup> described details of nervous innervation and attempted to correlate the fine structure with known biochemical reactions in light production.

Specimens for electron microscopy were prepared in the following manner. Female animals were killed by decapitation and appropriate pieces of the light organs of abdominal segments 5 and 6 were dissected out. Light organs also occur in the male but are considerably smaller and were considered inconvenient for use in this investigation. The pieces were fixed in 1 per cent potassium permanganate<sup>6</sup> or 1 per cent osmium tetroxide solution (both buffered with veronal acetate at pH 7.4) for 3 h. They were dehydrated in graded ethanols and embedded in 'Araldite'<sup>7</sup>. Sections were cut on a Porter-Blum ultra-microtome and mounted on carbon-coated grids. Sections were stained with 1 per cent uranyl acetate in absolute ethanol for 30 min at 50° C, or with lead citrate for 30 min at room temperature<sup>8</sup>, and examined with a Siemens Elmiskop electron microscope. The original magnifications used were from c. × 4,000 to 20,000, usually about 10,000. Osmium-fixation was not very successful for this particular tissue.

The light organs consist of four main parts: a transparent cuticle, a hypodermis, a photocyte cell layer several cells thick, and a single layer of cells comprising the reflector layer. Photocyte cells contain photocyte granules and a vesiculated reticulum (Fig. 1).

The reticulum joins the nuclear membrane (Fig. 2), and in every section of a nucleus the reticulum can be clearly seen to join as many as ten times (see Fig. 1).

It is not certain that it also joins the outer cell membrane, but it appears that it may do so (Fig. 3). The reticulum is invaginated, forming vesicles that vary considerably in size and shape, some being as large as average-sized photocyte granules (0.6 μ diameter). Some of these vesicles contain structures that have the appearance of photocyte granules in the course of formation (Fig. 4). In addition to these invaginations, it is likely that some of these vesicles are discrete structures and are not in con-

Fig. 1. General view of photocyte cells (permanganate fixed, uranyl acetate stained) showing amorphous granules (ag), mitochondria (m), nucleus (n), photocyte granules (pg) and the vesiculated reticulum (vr).

tinuity with the general cell cytoplasm. In osmium-fixed material the reticular vesicles can be seen to contain granules that are sited on the membranes and are probably ribosomes (Fig. 5).

Apart from the photocyte granules and mitochondria, the photocyte cells also contain amorphous 'granules' which may be the same as the "differentiated zone granules" of Smith<sup>6</sup> and the "granules containing dense material" of Kluss<sup>4</sup>.

A hypothesis is that the photocyte granules are produced by the reticulum and then released into the general cell cytoplasm. The granules may then release their contents in some way and light production occurs. Following light production, the granules may revert to "differentiated zone granules". Alternatively it could be that following light production the photocyte granules

Fig. 2. The vesiculated reticulum joining the nuclear membrane (nm) in a complex fashion (permanganate fixed, uranyl acetate stained)

Fig. 3. The vesiculated reticulum showing it apparently joining the nuclear membrane and outer cell membrane (om) (permanganate fixed, lead citrate stained)

Fig. 4. The vesiculated reticulum possibly containing a photocyte granule *pg* (permanganate fixed, uranyl acetate stained)

Fig. 5. The vesiculated reticulum showing the contained granules, probably ribosomes (osmium tetroxide fixed, lead citrate stained)

are taken into the vesiculated reticulum and broken down there. The circumstantial evidence for the association of the reticulum with granule production and hence light production is that neither the granules nor the vesiculated reticulum are present in the so-called reflector layer ("dorsal cell layer" of Smith<sup>5</sup>) although there is normal endoplasmic reticulum. What the photocyte granules contain is purely conjectural; for example, it could be a luciferin-luciferase complex. Previous investigations of other tissues have at least established the granule producing function of the Golgi apparatus<sup>9</sup>. Approximate calculations show that the photocyte granules take up about 1 per cent of the total cell volume (not including the nucleus) so the reticulum would seem quite capable of producing this quantity.

It is possible that this unusual reticulum is peculiar to glow-worm light organs. However, permanganate fixation, which fixes mainly membranes<sup>6</sup>, does not appear

have previously been used for fire-fly light organs, and this could explain the apparent absence of the vesiculated reticulum in previous investigations. With osmium tetroxide the reticulum is, to a certain extent, masked by the subsequent staining of additional structures.

We thank Prof. J. Z. Young and Dr. E. G. Gray for their encouragement and Miss C. Deane and Mr. S. Waterman for help with the photographs.

## SELENO-CYSTATHIONINE, A PHARMACOLOGICALLY ACTIVE FACTOR IN THE SEEDS OF *Lecythis ollaria*

### Cytotoxic and Depilatory Effects of Extracts of *Lecythis ollaria*

COCO de mono (*Lecythis ollaria*), or 'monkey nut', is a large deciduous tree widely distributed in Central and South America. In certain parts of Venezuela, ingestion of the nuts of this tree can produce a toxic syndrome in man<sup>1</sup>. The acute symptoms include abdominal discomfort, nausea, vomiting and diarrhoea. A striking feature of the syndrome is the loss of scalp and body hair a week or two after ingesting the nuts, after the initial acute phase has terminated. The alopecia is not permanent, and new hair grows.

It seemed possible that this alopecia could be due to the presence of a cytotoxic factor affecting the hair follicle itself, since most of the cytotoxic agents used in cancer chemotherapy can also produce hair loss<sup>2</sup>. Consequently, extracts of these nuts were tested for cytotoxic activity using mammalian cells (mouse fibroblasts) growing *in vitro* as the test system. The methods employed have been described previously<sup>3</sup>; briefly, replicate cultures of mouse fibroblasts (Earle's 'L' cells<sup>4</sup>, in 20 ml. Eagle's<sup>5</sup> medium) are established in 8-oz. prescription bottles. The number of cells in each of a representative group of bottles (3 bottles per group) is determined the following day, and sterile test solutions (volumes no greater than 2 ml.) are added directly to the culture medium of the experimental groups. The cultures are then returned to the incubator (37° C) for a period of five days. Cell counts are obtained with a Coulter electronic cell counter. Controls are always included; these will generally reveal 10- to 30-fold multiplication of the 'day 1' cell count ( $2 \times 10^6$  cells/bottle) after five days of incubation. The experimental bottles will have a variable number of cells; this is conveniently expressed as a percentage of the control growth.

Nuts were obtained from a tree in the western plains of Venezuela (state of Portuguesa) which was known to produce a nut toxic to man. The shelled, crushed nuts were extracted first with benzene, then sequentially with ethanol, water, and finally 10 per cent sodium chloride. These various fractions were tested for cytotoxic activity in the tissue culture system. Benzene and ethanol were removed by evaporation before testing; the oily residues were suspended in water. A marked inhibition of growth was found with water extracts of these nuts; the other actions were inactive. Using the tissue culture system as a bioassay, it was readily shown that the water-soluble, active material was dialysable and heat stable (boiling water bath, 5 min) in both acid and alkaline solutions. It was insoluble in ethanol, and could not be extracted into chloroform from acid or alkaline aqueous solutions. Incineration of the samples was done by a dry method (direct incineration in an ignition tube) and the appearance of a light red deposit (now realized to be red selenium) as noted at the upper end of the tube. The residual ash was dissolved in water and tested for cytotoxicity; it was inactive. Wet ignition was done with concentrated

sulphuric and nitric acid, boiling off the nitric acid. Water was then added, the sample neutralized, and tested for activity. All cytotoxic activity was lost in this procedure also, demonstrating the organic nature of the active agent. The biologically active material was well absorbed from neutral solution on 'Dowex-50' (H<sup>+</sup>), and (partially) on 'Dowex-1' (Cl<sup>-</sup>) from an alkaline solution.

A concentrated extract of coco de mono was prepared as follows: 68 g shelled crushed nuts were extracted with benzene and the residue suspended in 200 ml. water. This was placed in dialysis tubing and dialysed for 2 days against 5 l. distilled water at 3° C. The dialysis bath was changed once, after 24 h. The combined dialysates were reduced in volume to 70 ml. on a rotary evaporator, and shaken vigorously with chloroform to remove traces of proteins or lipids. The resulting clear yellow solution was assayed for cytotoxicity. Further purification was effected by ion exchange chromatography on a 'Dowex-50' (H<sup>+</sup>) column (Fig. 1). Biologically active material was obtained when the concentrations of KCl reached 1 M. Optical density at 260 mμ was also determined since it seemed at first to be associated with biological activity. However, purer samples of the biologically active material had little ultra-violet absorbing property. The two chromatographic fractions (numbers 24 and 25) showing biological activity were combined, and a yellowish hygroscopic material (30.5 mg) obtained by the addition of ethanol. Bioassay (Fig. 2) of this material revealed a 50 per cent inhibition of growth of mouse fibroblasts at a concentration of about 4 μg/ml., and about 80 per cent of the biological activity present in the original aqueous extract of coco de mono was accounted for in these two chromatographic fractions.

At about this time a group of chemists at Wyeth Laboratories<sup>6</sup> succeeded in isolating a larger quantity of pure crystalline material from these nuts which they identified as seleno-cystathionine, the selenium-containing analogue of the sulphur amino-acid, cystathionine. A comparison of the chemical and biological properties of the material obtained in the two laboratories showed them to be similar in every respect.

Attempts were made to reverse the cytotoxic effect of seleno-cystathionine by the addition of a variety of sulphur-containing compounds. It was observed (Table 1) that *L*-cystine (but not *D*-cystine) was effective in blocking the cytotoxic effect of seleno-cystathionine, and *D,L*-allo-cystathionine and *L*-cystathionine were also effective, although not as active in this respect as *L*-cystine. Other sulphur-containing compounds such as reduced glutathione, homocystine and mercaptoethanol could not be shown to have any effect. *L*-Cysteine was toxic to the cells in concentrations greater than 10 μg/ml. (possibly by chelating trace metals in the culture medium), but a slight protective effect could be demonstrated with *L*-cysteine if 200 μg (that is, 10 μg/ml. final concentration in the culture medium) was added daily during five days incubation with 10 μg/ml. seleno-cystathionine. Cystine was equally effective in blocking the cytotoxic effects of

Fig. 1. Chromatographic purification of cytotoxic material from an aqueous extract of coco de mono. An aqueous extract was prepared as described in the text, and a portion representing 30 g of shelled nuts was applied to a 'Dowex-50'  $\times$  4(H<sup>+</sup>) column, 11  $\times$  120 mm. It was washed through with water, and elution was begun with increasing concentrations of KCl. Fractions of 25 ml. each were collected. Optical density at 260 m $\mu$  was determined directly, and biological activity was determined by testing the effect of 0.1 ml. of each fraction on mouse fibroblasts growing *in vitro*, as described in the text

Fig. 2. Dose-response curve to an aqueous solution of purified material from coco de mono. Material obtained from fractions 24 and 25 (Fig. 1) was dissolved in 0.01 N HCl at a concentration of 1 mg/ml. Various amounts of this solution were added to mouse fibroblasts growing *in vitro*, as described in the text. The volume of culture medium used was 15 ml.; hence, the IC<sub>50</sub> (concentration required for 50 per cent inhibition of growth) is about 4  $\mu$ g/ml. in this experiment. The mean and standard errors of groups of three bottles are indicated on the figure

seleno-cystathionine, or of crude water extracts of coco de mono. This fact, plus the fact that virtually all the cytotoxic activity present in water extracts of coco de mono was accounted for by the seleno-cystathionine isolated, leads us to suggest that while there may be other selenium-containing compounds present in these nuts, cytotoxic activity seems to be due solely to seleno-cystathionine.

Seleno-cystathionine was first isolated, as a 2 : 1 mixture with cystathionine, from *Astragalus pectinatus* by Horn and Jones<sup>7</sup> in 1941. More recently, it has been detected

Table 1. REVERSAL OF SELENO-CYSTATHIONINE TOXICITY

Various compounds were added to the culture medium, in the presence and absence of a toxic concentration of seleno-cystathionine, in an effort to reverse the growth-inhibitory effect of the selenium-containing amino-acid. All agents and the seleno-cystathionine were added to the culture medium or the day after inoculation of the bottles. The results are given as a percentage of the control growth, after 5 days of incubation, expressed as the mean of a group of three bottles.

Culture medium supplemented with:	Without seleno-cystathionine (%)	With seleno-cystathionine, 10 $\gamma$ /ml (%)
Nothing	100	7
<i>l</i> -cystine, 10 $\gamma$ /ml.	111	11
<i>l</i> -cystine, 100	108	89

in *Stanleya pinnata* by Virupaksha and Shrift<sup>8</sup>. However the larger part of organic selenium in the selenium accumulating plants *Astragalus bisulcatus*, *A. crotalaria*, and *Oenopsis condensata* seems to be Se-methylseleno-cysteine<sup>9,10</sup>, and it seems likely that this is the organic form of selenium present in several plants which is responsible for the livestock diseases called 'blind-staggers' and 'alkali disease'.

Human intoxication with seleniferous plant material has not been extensively described, although it is known to occur in parts of Colombia, South America<sup>11</sup>. Report of hair loss associated with toxic foods go back as far as 1560 in that part of the world. In the United States hair loss associated with selenium poisoning has been reported among certain Indians<sup>12</sup>. Weisberger and Suhrlund<sup>1</sup> administered synthetic *d,l*-seleno-cystine to a few patient with leukaemia and reported severe toxicity with symptoms of persistent and severe nausea, vomiting, anorexia and hair loss, a syndrome strongly resembling the toxic effects seen in man after ingesting coco de mono.

This work was supported by a research grant (CA05672 from the U.S. Public Health Service. We thank Dr. M Granier-Doyeux, and the members of the Instituto de Medicina Experimental, Universidad Central de Venezuela, for their warm hospitality to one of us (L. A. during the course of this work.

### Structure of the Pharmacologically Active Factor in the Seeds of *Lecythis ollaria*

It has been known for many years that the Brazil nut like seeds of *Lecythis ollaria*, or coco de mono, a large deciduous tree indigenous to Venezuela, contain a factor which will produce alopecia and a variety of other pharmacological manifestations<sup>1</sup>. It was therefore of interest to determine the chemical structure of the agent or agents responsible for these effects.

Paper chromatography of crude aqueous extracts showed the presence of one intense, three moderate, and at least three very weak ninhydrin-positive spots. The major component was well differentiated from most common amino-acids and mimosine in standard paper chromatographic systems: *n*-butanol/propionic acid/water 10 : 5 : 7, *n*-butanol/pyridine/water (1 : 1 : 1), and phenol/water (5 : 2). Since the major component had ion exchange properties similar to those found in preliminary isolation experiments based on tissue culture cytotoxicity, subsequent purification steps were guided by paper chromatography.

A satisfactory isolation scheme was developed as illustrated in the following example. Unshelled nuts (2.6 kg) were ground in a Waring blender and the solids defatted first for 1 h with 4 l. of benzene at room temperature and then with 3 l. of ethanol at 60° C. The residue was extracted with 6 l. of water at 80° C for 1.5 h. The filtrate was concentrated to 200 ml. and dialysed against 18 l. of cold distilled water. The dialysate was concentrated to 1.1 l., adjusted to pH 11.0 with sodium hydroxide, and centrifuged. The supernatant solution was passed through a 40 × 1.8 cm column of 'Dowex-1' × 10 (Cl<sup>-</sup>). The adsorbed active compound was then eluted with 1 M pyridine-acetic acid buffer, pH 6.7, and the fraction with the highest amino-acid content, as determined by ninhydrin assay<sup>3</sup>, was concentrated 10-fold and then chilled, with the resulting deposition of 250 mg of needle-shaped crystals. Gradual addition of ethanol in the cold yielded an additional 650 mg of crystals which were structurally and chromatographically identical with the original crystals.

Infra-red analysis of the crystals strongly pointed to an amino-acid and showed no hydroxyl, amide, or phenyl groups, while ultra-violet spectra showed only end-absorption. Nuclear magnetic resonance spectra in deuteronium oxide suggested an asymmetrical compound with no methyl groups. Qualitative assays showed a high selenium content, which, together with the other properties observed, suggested that this was one of the selenium analogues of the natural sulphur amino-acids previously observed in grasses and legumes grown in seleniferous areas<sup>3-6</sup>. Paper chromatography, elemental analysis, and various colour tests readily eliminated the selenium analogues of numerous —S—S—, —SH, —S—CH<sub>2</sub>—S— and —S—R— compounds, and led to the possibility of a *bis* compound with a single selenium atom, such as a selenium ether: HOOC—CH(NH<sub>2</sub>)—(CH<sub>2</sub>)<sub>n</sub>—Se—(CH<sub>2</sub>)<sub>m</sub>—CH(NH<sub>2</sub>)—COOH. The compound was therefore subjected to Raney nickel hydrogenolysis by the procedure of Mozingo *et al.*<sup>7</sup> to remove the selenium. The products were chromatographed, using the three paper chromatographic procedures described here, and the only components found were alanine and α-amino butyric acid. These results indicated that the compound was the selenium analogue of either cystathionine or β-methylanthionine: HOOC—CH(NH<sub>2</sub>)—CH<sub>2</sub>—Se—CH<sub>2</sub>—CH<sub>2</sub>—

CH(NH<sub>2</sub>)—COOH or HOOC—CH(NH<sub>2</sub>)—CH<sub>2</sub>—Se—CH(CH<sub>3</sub>)—CH(NH<sub>2</sub>)—COOH, respectively.

The infra-red spectrum of the isolated compound was practically identical with a published spectrum for cystathionine<sup>8</sup>, and the nuclear magnetic resonance data eliminated β-methylanthionine. Throughout the foregoing work some sulphur was present, presumably due to the crystallization of cystathionine with the selenium analogue, as had been observed by Horn and Jones<sup>4</sup>. Subsequent recrystallization, however, yielded an essentially sulphur-free product with the following elemental analysis: calculated for C<sub>7</sub>H<sub>14</sub>N<sub>2</sub>O<sub>4</sub>Se: C, 31.3; H, 5.2; N, 10.4; Se, 29.4. Found: C, 31.3; H, 5.2; N, 10.0; Se, 29.2. The optical rotation was +36.5° (1 per cent in 1 N hydrochloric acid).

Incubation with D-amino-acid oxidase and subsequent chromatography showed no loss of the starting material and thus the compound would seem to be L-2-amino-4-[(L-2-amino-2-carboxyethyl)selenyl]butyric acid or cysta-selenonine.

Recent investigations by Aronow<sup>10</sup> have shown the crystalline product to produce the same type of toxicity in rats as crude aqueous extracts of the *Lecythis ollaria* seeds.

The previously described principal source of the selenium analogue of cystathionine is *Astragalus pectinatus* ('loco weed') of the western United States<sup>4</sup>, but Virupaksha and Shrift<sup>9</sup> have recently shown by methods similar to those reported here that the compound is also produced by *Stanleya pinnata*. The present results add a new genus, *Lecythis*, to those known to produce selenium amino-acids<sup>11</sup>. To our knowledge, plants containing more than trace amounts of selenium have not been previously observed on the South American continent.

## EFFECT ON MYXOVIRUS OF MITOMYCIN C, ACTINOMYCIN D, AND PRETREATMENT OF THE HOST CELL WITH ULTRA-VIOLET LIGHT\*

By RUDOLF ROTT, SAMI SABER and CHRISTOPH SCHOLTISSEK

Institut für Virologie der Justus Liebig-Universität, Giessen, Germany

THE results previously obtained concerning the multiplication of influenza viruses suggest that host-cell DNA plays an important part<sup>1</sup>. This conclusion has been drawn from the following evidence: Although

\* The experiments were performed in part at the Max-Planck-Institut für Virusforschung, Tübingen.

influenza viruses contain single-stranded ribonucleic acid (RNA)<sup>2</sup>, their multiplication can be inhibited by actinomycin D<sup>3,4</sup>, which is known to interfere with the template function of DNA<sup>5-8</sup>. Furthermore, if the host cell is pretreated with ultra-violet light and then infected with an influenza A virus (fowl-plague virus), there is no multiplica-

tion of the virus as measured by haemagglutination<sup>1</sup>. On the other hand, synthesis of new DNA is not necessary for multiplication of fowl-plague virus, since this is not influenced by the DNA-inhibitor aminopterin<sup>2</sup>. Thus, while agents which render the host-cell genome non-functional, or which inactivate it, prevent the formation of influenza viruses, inhibitors of DNA synthesis do not.

By way of contrast, another myxovirus, Newcastle disease virus (NDV), multiplies normally in actinomycin-treated cells<sup>3,4</sup> or in ultra-violet-irradiated cells<sup>1</sup>.

This article is concerned with the action of some agents which react with, or inactivate, host-cell DNA, and reports experiments carried out to determine whether or not the host DNA does influence the multiplication of influenza viruses.

The 'Rostock' strain of fowl-plague virus and the 'Italien' strain of NDV were used throughout. Methods concerning the preparation of tissue cultures and their infection and the assays and chemicals used have already been described<sup>5</sup>. Ultra-violet irradiation of the tissue cultures was performed in the absence of medium with an ultra-violet lamp (NK 20/40 V, Quarzlampengesellschaft, Hanau, Germany) at a distance of 32 cm. The actinomycin D used was a gift of Merck, Sharp and Dohme, New York. Mitomycin C was obtained from the Sigma Chemical Co., St. Louis, Missouri.

(1) *Influence of pretreatment of host cells with mitomycin C or ultra-violet light on the multiplication of myxoviruses.* Mitomycin C and ultra-violet light are known to destroy the cell genome<sup>10-12</sup>. If cell DNA were necessary for the multiplication of fowl-plague virus, it is conceivable that pretreatment with this antibiotic or ultra-violet light would have an inhibitory effect on the formation of this virus but not on NDV.

Mitomycin C does not influence the isolated virus particles so far as infectivity and haemagglutination are concerned. The effect of mitomycin C on the multiplication of fowl-plague virus and NDV was tested by addition of different doses of the antibiotic to the cultures immediately after infection. Seven or eight hours later, respectively, the infectivity, haemagglutination, neuraminidase, and complement-fixing (CF) activity were tested in the disrupted cells. The results are shown in Table 1. The antibiotic inhibits the formation of all components of fowl-plague virus but not of NDV. However, the synthesis of the various components of fowl-plague virus shows different sensitivities to the action of mitomycin.

Table 1. INFLUENCE OF DIFFERENT DOSES OF MITOMYCIN C ON THE MULTIPLICATION OF FOWL-PLAGUE AND ND VIRUSES

	Fowl-plague virus				NDV			
	$\mu\text{g/ml.}$	HA-units	Neuraminidase $\mu\text{g}$	CF-titre	HA-units	Neuraminidase $\mu\text{g}$	CF-titre	
	mitomycin	P.F.U.	NANA/ml.	Q	P.F.U.	NANA/ml.	Q	
0	1,024	$3.7 \times 10^7$	226	4.8	128	$2.3 \times 10^7$	40.5	3.7
10	1,024	$4.1 \times 10^7$	251	3.7	128	$8.0 \times 10^7$		3.7
20	64	$2.7 \times 10^7$	110	3.7	128	$9.2 \times 10^7$		3.7
30	16	$3.2 \times 10^6$	28.5	3.3	128	$1.0 \times 10^8$		3.7
40	2	$1.6 \times 10^6$	6.2	2.9	64	$3.0 \times 10^7$	32.5	3.7
50	2	$1.0 \times 10^6$		2.2	64	$1.5 \times 10^7$		3.3
60	2	$1.2 \times 10^6$			64	$2.3 \times 10^7$		

Mitomycin was added immediately after infection. The virus activities were determined in the cell layers 7 h post infection (fowl plague) or 8 h post infection (NDV), respectively, after freezing/thawing the cells three times and after removal of the cell debris by centrifugation. The yields in the incubation medium were negligible. The residual virus not removed by the washing procedures from the infected cells was about  $10^6$  P.F.U.

In another experiment 40  $\mu\text{g/ml.}$  of the antibiotic was added to the cultures several hours before infection and was removed either immediately after, or 2 h before, the cultures were infected. Even when the time of mitomycin action on the host cell was greater than 1 h, inhibition of the production of fowl-plague virus could still be detected in the absence of the antibiotic (Table 2). Addition of mitomycin 1 h or more after infection had no significant

Table 2. INFLUENCE OF PRETREATMENT OF THE HOST CELLS WITH MITOMYCIN C ON THE MULTIPLICATION OF FOWL-PLAGUE AND ND VIRUSES

Time of addition of mitomycin C (h)	HA-units	Fowl-plague virus		NDV	
		Neuraminidase $\mu\text{g}$	CF-titre	Neuraminidase $\mu\text{g}$	P.F.U.
		NANA/ml.	Q		
5 (a.i.)	4	10.8	4.8		$1.2 \times 10^8$
3 (a.i.)	128	48.5	4.8		$1.5 \times 10^8$
1 (a.i.)	512	142	4.8		$2.1 \times 10^8$
1 (p.i.)	512	220	4.8		$1.4 \times 10^8$
3 (p.i.)	1,024	195	4.8		$8.5 \times 10^8$
5 (p.i.)	1,024	270	4.8		$8.0 \times 10^8$
No mitomycin	1,024	212	4.8		$1.2 \times 10^8$

40  $\mu\text{g/ml.}$  mitomycin C was added at different times before infection (a.i.). Mitomycin was removed by several washings immediately after the infection, and the cells were further incubated without the antibiotic. In those cases when mitomycin was added at different times after the infection (p.i.) the antibiotic was not removed. For further details see Table 1. Essentially the same results have been obtained when the mitomycin was added 7, 5, and 3 h a.i. and removed 2 h before infection by change of the medium.

effect on the multiplication of fowl-plague virus. Formation of NDV is not affected by this antibiotic.

The results of the pretreatment of the host cells with ultra-violet light are summarized in Table 3. After a certain length of time of ultra-violet irradiation of the host cells prior to infection in the absence of medium the production of the fowl-plague components tested is inhibited. But, here again, the synthesis of the RNP-antigen is less sensitive to the pretreatment of the cells with ultra-violet light, as has been found with mitomycin. NDV multiplies normally in such cells pretreated with ultra-violet light. If the host cell genome is necessary for fowl-plague virus production, it should influence one of the very early events following infection, since pretreatment of the cells with ultra-violet light or mitomycin affects the synthesis of all virus components tested.

Table 3. INFLUENCE OF PRETREATMENT OF HOST CELLS WITH ULTRA-VIOLET LIGHT ON THE MULTIPLICATION OF FOWL-PLAGUE AND ND VIRUSES

Time of ultra-violet irradiation (sec)	HA-units	Fowl-plague virus		NDV	
		P.F.U.	CF-titre	HA-units	P.F.U.
			Q		
0	1,024	$5.3 \times 10^7$	3.3	128	$3.4 \times 10^7$
5	1,024	$9.8 \times 10^7$	3.3	256	$1.2 \times 10^8$
10	32	$8.5 \times 10^6$	3.3	256	$1.4 \times 10^8$
15	2	$1.8 \times 10^6$	2.5	256	$1.3 \times 10^8$
20	2	$1.2 \times 10^6$	2.2	256	$7.5 \times 10^7$
25	2	$1.8 \times 10^6$	2.2	256	$4.0 \times 10^7$
30	2	$1.3 \times 10^6$	1.9	256	$5.1 \times 10^7$
80	2	$8.0 \times 10^5$	1.14	128	$2.7 \times 10^7$

The cells were irradiated with different doses of ultra-violet light immediately before infection. For further details see Table 1.

(2) *Synthesis of fowl-plague RNA in the presence of actinomycin.* When actinomycin was added to cultures immediately following infection with fowl-plague virus the incorporation of  $^{14}\text{C}$ -uridine into RNA was only about 0.5 per cent of that found in non-infected cells without actinomycin. If, however, the antibiotic was added 2 or 4 h post infection, the residual incorporation during a 1-h pulse went up to 4 per cent of the controls without actinomycin. Therefore, we characterized this RNA by determining its base composition and comparing it with fowl-plague RNA. The base composition of the viral RNA following digestion with alkali can be seen in Table 4.

Since there is still relatively high labelling in the 2', 3'-CMP-fraction of the soluble RNA in non-infected cells (following alkali digestion) in the presence of actinomycin<sup>15</sup>, this fraction was separated in a sucrose gradient from the  $^{32}\text{P}$ -labelled high-mol. wt. RNA of fowl-plague-infected cells. The results concerning newly synthesized RNA-fractions in actinomycin-treated and fowl-plague-infected cells are summarized in Table 4 (experiments 5 and 6). The radioactivity was never found in a single peak, which might be due to the inability to isolate an unbroken fowl-plague RNA<sup>16</sup> or to its destruction by actinomycin (see later). Up to 80 per cent of the total radioactivity in experiment 5 is found in the 23S and 16S fractions. Since the base composition of this RNA is

	Cellular RNA*	29.0	20.1	20.0	30.9	

For the labelling of viral RNA in each experiment 5 infected cultures each received 1 mc. of  $^{32}\text{P}$  immediately after infection. 8 h p.i. the virus particles were isolated from the supernatant medium without disrupting the cells<sup>12</sup>. In experiments 5 and 6, 10 cultures each received 1 mc. or 0.2 mc.  $^{32}\text{P}$ , respectively, 2 h p.i. together with 5  $\mu\text{g}/\text{ml}$ . actinomycin. The RNA was extracted 5 h p.i. and fractionated in a sucrose gradient<sup>14</sup>.

\* Taken from Scholtissek and Rott (ref. 23).

close to that of fowl-plague RNA, it is concluded that about 80 per cent of the RNA newly synthesized under the conditions used is viral RNA.

These results suggest that actinomycin is able to reduce the synthesis of fowl-plague RNA, but does not inhibit it completely, if the antibiotic is added after the beginning of viral RNA synthesis. Therefore, experiments were performed to determine how far incubation of the host cells with actinomycin influences this viral RNA synthesis. For this purpose the antibiotic was added to different cultures 2, 4 or 6 h post infection. The cultures were then treated with  $^{14}\text{C}$ -uridine between 6 and 7 h post infection. As shown in Fig. 1, the incorporation of  $^{14}\text{C}$ -uridine increased as the interval between infection and addition of actinomycin increased. The inverse experiment was carried out by adding the antibiotic in all cases 2 h post infection, but the  $^{14}\text{C}$ -uridine was given at different times thereafter. The later the  $^{14}\text{C}$ -uridine was added the less was the incorporation. These results are shown together with corresponding controls in Fig. 1.

Fig. 1. Action of actinomycin on the incorporation of  $^{14}\text{C}$ -uridine into the RNA of cells infected with fowl-plague virus: x, 5  $\mu\text{g}/\text{ml}$ . actinomycin plus 1  $\mu\text{C}$ .  $^{14}\text{C}$ -uridine were added at the time p.i. as indicated on the abscissa; Δ, the actinomycin was added at the times indicated on the abscissa, and the  $^{14}\text{C}$ -uridine was added between 6 and 7 h p.i.; O, the actinomycin was added 2 h p.i., the  $^{14}\text{C}$ -uridine at the times as indicated on the abscissa. One hour later the radioactivity was determined in the RNA. All values were corrected for the residual incorporation of  $^{14}\text{C}$ -uridine into non-infected cells in the presence of actinomycin.

The results show that viral RNA synthesis—as soon as it has started—can be suppressed completely by actinomycin only when the infected cells are incubated with this antibiotic for at least 4 h. This is in contrast to the inhibition of cellular RNA synthesis, which occurs almost immediately<sup>4</sup>.

Pre-incubation of NDV-infected cells with actinomycin had only little effect on the synthesis of NDV-RNA. The greatest incorporation of  $^{14}\text{C}$ -uridine (given 6.5–8.5 h post infection) occurred when the antibiotic was added 4 h post infection (about 30 per cent of non-infected cells without actinomycin).

The multiplication of fowl-plague virus can be inhibited by actinomycin *D*<sup>4</sup>, by mitomycin *C*, and by pretreatment of the host cells with ultra-violet light<sup>1</sup> or mitomycin *C*. Since these treatments had no effect on the formation of NDV, it was conceivable that the host cell genome played an important part in the multiplication of influenza viruses, of which fowl plague is a member<sup>1,3</sup>. It is most unlikely that the total viral genome is coded by the host cell; but it is possible that one step during the multiplication common to all influenza strains is controlled by the host DNA. If this were the case, then this step would have to occur very early in the multiplication cycle, because the addition of actinomycin *D* immediately after infection completely prevents the formation of the first-appearing viral component—namely the viral RNA. Once viral RNA synthesis has started (2 h post infection), the addition of actinomycin does not inhibit the formation of viral RNA immediately. It requires about 4 h incubation with the antibiotic before its synthesis is blocked completely (Fig. 1). This result could be interpreted in the following way: For viral RNA synthesis the presence of a protein is necessary, which is coded by the cell genome, and the synthesis of which is induced by the infection. Furthermore, it should be relatively unstable and must be continually newly synthesized in order to keep the viral RNA synthesis going.

This interpretation is contradicted by the following fact: An 'early protein' necessary to start the synthesis of fowl-plague RNA has been demonstrated by using the amino-acid analogue *p*-fluorophenylalanine<sup>2,17</sup>. This 'early protein' is completely stable for at least 4 h. The design of the experiment excludes a second unstable protein necessary for the start of viral RNA synthesis. Therefore, a direct participation of the host-cell DNA during the multiplication of fowl-plague virus is rather unlikely.

We must therefore consider another possibility in order to explain the results. There exist several reports concerning breakdown of RNA by actinomycin<sup>18,19</sup> or mitomycin<sup>11</sup> which might not be explained by a normal turnover. It is conceivable that in a similar way fowl-plague RNA or its template is affected during the multiplication cycle by the agents mentioned. During the first hour following infection the few viral RNA molecules have no chance to establish an RNA-synthesizing centre in the presence of actinomycin. Later, when viral RNA synthesis has already started and many viral RNA molecules are present, it takes some time to inactivate all the fowl-plague RNA (or their templates for further RNA synthesis; see Fig. 1).

There are two points which are in favour of the latter interpretation: (1) If actinomycin is added 1.5–2 h post infection, the infectivity titre, when tested 6 h later, is just beginning to rise. At this time the plague test showed an effect which has been interpreted as multiplicity reactivation<sup>4</sup>. The same effect has been found during the inactivation of isolated fowl-plague virus with Bayer A 139 (ref. 20) or hydroxylamine<sup>21</sup>. Both compounds inactivate the viral RNA. (2) There was a different response to the synthesis of the distinct fowl-plague components using increasing doses of ultra-violet light or mitomycin, respectively (Tables 1–3). A corresponding effect has been observed during the stepwise degradation of the fowl-plague genome with Bayer A 139 or hydroxylamine<sup>22,23</sup>.

Nevertheless, the difference in response to these agents between the influenza viruses and NDV remains to be explained. It is known that the RNP-antigen and viral RNA of fowl plague are formed in the nucleus<sup>24,25</sup>. In NDV-infected cells, however, all virus material is synthesized in the cytoplasm<sup>26,27</sup>. We have some evidence that the RNA-degrading effect of actinomycin might be confined to the cell nucleus. Actinomycin does not influence protein synthesis for about 3 h after its addition to fibroblasts. This means that the templates (RNA) for protein synthesis, which occur in the cytoplasm, are not degraded directly by actinomycin. The late inhibition of protein synthesis by this antibiotic is probably due to an exhaustion in the cell of messenger RNA, which is no longer produced in the presence of actinomycin<sup>5-8</sup>.

According to our investigations a specific contribution of the cell genome to one of the early steps during the multiplication of influenza viruses is unlikely. There is no need for such an assumption, since the inhibitory effect of agents reacting with the cell genome might be explained by a destruction of the influenza genome in the cell nucleus without influencing the NDV multiplication in the cytoplasm.

## LOW-TEMPERATURE FLUOROGRAPHY INDUCED BY TRITIUM-LABELLED COMPOUNDS ON THIN-LAYER CHROMATOGRAMS

By DR. URSULA LÜTHI and PROF. P. G. WASER

Institute of Pharmacology, University of Zurich

**A**UTORADIOGRAPHIC methods have not yet found application to thin-layer chromatography of <sup>3</sup>H-labelled compounds because of the low tritium energy ( $E_{\max} = 18.5$  keV;  $E_{\text{mean}} = 5.7$  keV). The tritium range in a layer of sodium-*o*-(carboxymethyl) cellulose and in sodium alginate has been determined by Isbell, Frush and Peterson<sup>1</sup> to be 0.28 mg/cm<sup>2</sup>. The surface density of a 250- $\mu$  thin layer of silica-gel *G* or cellulose is 5.5 mg/cm<sup>2</sup> or 7.5 mg/cm<sup>2</sup>, respectively. This is about 20 times the tritium range, which means a self-absorption loss of radiation of more than 95 per cent.

If the thin-layer material is mixed with an adequate scintillator the tritium radiation can be made visible by the fluorescence induced in the scintillator, provided the scintillator molecules are within the range of the tritium  $\beta$ -particles and the thin layer is transparent for the fluorescence radiation. We therefore prefer the term 'fluorography' to the misleading name 'autoradiography'.

The maximum range of a tritium  $\beta$ -particle expressed in microns in a silica-gel layer of 250 $\mu$  can be calculated from its surface density and its thickness:

$$250 \times 0.28/5.5 = 12.7\mu$$

Two methods of using scintillators for fluorograms of tritium-labelled compounds have been described. Wilson<sup>2</sup> puts the paper chromatogram into a solution of scintillator (*p*-terphenyl in toluene), covers it with an X-ray film and leaves both chromatogram and film in the scintillator solution during exposure time. This method cannot be used for thin-layer plates, their surface being easily damaged by this procedure. Furthermore, the method is limited to compounds which are insoluble in the solvent of the scintillator.

Parups, Hoffmann and Jackson<sup>3</sup> dipped their paper chromatograms into a saturated benzene solution of anthracene and applied the X-ray film after evaporation of the solvent. The sensitivity of their method depends entirely on the amount of anthracene introduced into the chromatogram. They obtained a fluorograph of a minimal radioactivity of 0.38  $\mu\text{C}/\text{cm}^2$  after 7 days exposure.

The technique for thin-layer chromatography described here uses solid anthracene as a scintillator which is finely ground in a ball mill with an equal amount of silica-gel *G* (content of gypsum 13 per cent) from Merck, Darmstadt, to a crystal size of 1–5 $\mu$ . The diameters of the anthracene and silica gel crystals are thus about one-third of the maximum  $\beta$ -range of tritium. The low solubility of anthracene in most solvents under mild conditions makes this microcrystalline powder suitable as thin-layer material. 30 g of this mixture is added to 80 ml. of 96 per cent ethanol. After thorough shaking the suspension is spread over glass plates with a special distribution apparatus (furnished by Desaga, Heidelberg) and dried at room temperature. 30 g is sufficient for ten thin-layer plates (20  $\times$  10 cm<sup>2</sup>) 250 $\mu$  thick, their surface density being 5.5 mg/cm<sup>2</sup>. They can be used for most common solvent mixtures. Colour reagents which do not react with anthracene may be used for detection of the compounds. Fig. 1 shows the separation of a mixture of tertiary and quaternary compounds. Their chromatographic properties are the same as on pure silica gel except for slightly prolonged travelling times. Chromatograms of tritium-labelled compounds are covered with X-ray films ('Kodirex', Kodak) and exposed over dry ice at  $-70^\circ\text{C}$ . 0.08  $\mu\text{C}$  of tritium can be detected after exposure for one day (Fig. 2). Control experiments have to be made with the

unlabelled compound. When no fluorescence picture develops after the same exposure time at  $-70^{\circ}\text{C}$ , the blackening of the film is only due to tritium-induced fluorescence.

Low temperature during exposure is essential. A tritium-induced fluorograph is twice as intense when exposed at  $-30^{\circ}\text{C}$  than at  $+4^{\circ}\text{C}$  and 30 times as intense at  $-70^{\circ}\text{C}$ . No increase of film blackening is obtained by further lowering the temperature to  $-200^{\circ}\text{C}$  (Fig. 3). These amplification values were obtained by densitometric measurements of the films. A similar, but much slighter, effect was produced with a mixture of silver-activated zinc sulphide and  $\text{SiO}_2$ . A similar dependence on temperature was observed with red-light-induced fluorescence of anthracene by Singh and Lipsett<sup>4</sup>. The temperature variation of the scintillator response seems to be correlated with the vibrational freedom of the molecules. At low temperature vibration is 'frozen in' and less energy is lost for radiationless transitions<sup>5</sup>.

Fig. 1. Chromatogram of an amine mixture on an anthracene/silica gel 1/1 thin layer ( $250\mu$  thick). 1, Hexamethonium; 2, *Bis-N*-dimethyl-hexamethylenediamine; 3, Trimethylamine; 4, Mixture of 1, 2, and 3. Solvent: acetonitril/ $\text{HCl}/\text{H}_2\text{O}$  (7/2/1). Colour reagent: Dragendorff-reagent

Fig. 2. Fluorogram of tritium labelled diallyl-nor-toxiferine ('AlloferinR'). a, On silica-gel G; b, on anthracene/silica-gel G (1/1). Exposure time: 18 h at  $-70^{\circ}\text{C}$ . Solvent: acetonitril/hexane/diethylamine (75.5/17.5/5)

Fig. 3. Fluorograph of tritium ( $^3\text{H}$ -'AlloferinR') on anthracene/silica gel (1/1) exposed at various temperatures. Exposure time: 18 h

The application of the technique described here to  $^{14}\text{C}$ -labelled compounds shows no advantage over the ordinary contact autoradiography. No increase of film blackening was obtained by a  $^{14}\text{C}$  compound on anthracene/silica gel when compared with the blackening on silica gel without the scintillator. The  $\beta$ -energy of  $^{14}\text{C}$  is about ten times that of  $^3\text{H}$ . Therefore, a  $^{14}\text{C}$   $\beta$ -particle is more likely to react with the photographic emulsion than with the microcrystals of the thin layer.

The method described is an application of fluorography to thin-layer chromatography of tritium-labelled compounds. It takes advantage of four properties of anthracene: its high fluorescence efficiency; the temperature dependence of its fluorescence intensity; its low solubility in most of the common solvents; its low chemical reactivity.

This method could be further improved by raising the ratio anthracene/silica gel. The amplification of tritium-induced fluorescence on pure anthracene is about 15 times higher than on mixtures containing 50 per cent anthracene. Anthracene thin layers are easily prepared, with 10 per cent gypsum or with small amounts of detergents such as sodium-lauryl-sulphonate. However, some substances investigated in our laboratory (tertiary and quaternary ammonium compounds) did not separate on anthracene thin layers. The purity of the anthracene is not of primary importance. Both the scintillation and the purum grade gave equal results. Shifting of the anthracene fluorescence spectrum produced by trace impurities has no influence on X-ray films.

## POSSIBILITY OF NON-THERMAL IONIZATION COMBUSTION PRODUCT MAGNETOHYDRODYNAMIC GENERATORS

By D. V. FRECK and J. K. WRIGHT

Central Electricity Research Laboratories, Cleeve Road, Leatherhead, Surrey

**W**HEREAS it is widely accepted that some form of non-thermal ionization is likely to be practical with closed-cycle magnetohydrodynamic generators, the possibility of obtaining significant reductions in working temperature for a given electrical conductivity in open-cycle combustion product magnetohydrodynamic generators is normally considered to be remote. In this article the various methods of obtaining such enhanced conductivity are reviewed and it is shown that magnetically induced ionization may possibly give a significant increase in conductivity.

The possibility of making use of the relatively long recombination times at low temperatures has been briefly discussed elsewhere<sup>1</sup> and is not included here, since it will only give the ionization appropriate to the temperature somewhat earlier in the magnetohydrodynamic generator. The methods discussed here are: (1) by causing excessive ionization from an external source, for example, ultra-violet lamp, radio-frequency breakdown, electron beam injection, etc.; (2) by using the currents flowing in the gases to cause an increase in ionization by raising the electron temperature; (3) by using the non-equilibrium effects that occur when chemical reactions occur in flames to raise the electron temperature.

Before discussing these in detail, it is desirable to discuss the orders of magnitude of various important parameters governing the departure from equilibrium. In a magnetohydrodynamic generator of the type that might be used on a power station, the temperature falls from about 2,500° K at the entrance to the duct to about 2,000° K at the exit, the pressure falling from perhaps 5 to 1 atm. and the electron density from perhaps  $10^{14}$  to  $10^{13}$  electrons/c.c. The length of time a volume of gas takes to pass along a full-scale magnetohydrodynamic generator is typically  $10^{-2}$  sec.

Suppose energy has been given to the electrons in some manner. The electrons interact with each other in a time of order  $6,000/n$  sec if the electron temperature is of the order 2,000° K. The Maxwell tail capable of ionizing potassium will take rather longer to form—a time of order  $5 \times 10^6/n$  sec ( $n$  is the electron density).

The time taken for ionization of the potassium may now be calculated. The ionization process may be described by an equation of the form:

$$\frac{dn_e}{dt} = 6 \times 10^{-24} (n^2 n_e - n^3_e)$$

The constant  $6 \times 10^{-24}$  refers to 2,000° K; it varies inversely as the sixth power of the temperature. Hence, near equilibrium:

$$\frac{dn_e}{dt} = 1.2 \times 10^{-23} n^2 (n_e - n)$$

and an ionization time constant,  $8 \times 10^{22} n^{-2}$  sec.

Electrons can lose energy by inelastic collisions with molecules. In combustion products, the probability of energy loss is greatest with  $\text{CO}_2$  and  $\text{H}_2\text{O}$ . The time constant for this process has been calculated from the data of Healey and Reed<sup>2</sup> and would be  $10^{-10}$  and  $5 \times 10^{-10}$  sec at the duct entrance and exit respectively.

If the electron temperature were maintained at a given level, the vibrational energy-levels of the molecules (assumed decoupled from the translational states for the moment), would gradually attain the electron temperature.

The time constant would be equal to the electron cooling time constant multiplied by the ratio of the number of molecules to electrons. The time constants are therefore  $5 \times 10^{-6}$  and  $5 \times 10^{-5}$  sec at the duct entrance and exit respectively.

However, the vibrational relaxation times are very short in  $\text{CO}_2$ ,  $\text{H}_2\text{O}$  mixtures, being of the order of  $10^{-7}$  and  $6 \times 10^{-7}$  sec at the duct entrance and exit respectively.<sup>3</sup>

The results of these calculations are given in Table 1. Some conclusions can be drawn immediately. All the times are short compared with the time for a gas element to flow through the duct. Hence a steady state is reached in all phenomena.

Table 1  
Times (sec)

	Duct entrance	Duct exit
Flow through duct	$10^{-2}$	$10^{-2}$
Electron-electron energy exchange	$6 \times 10^{-11}$	$6 \times 10^{-10}$
Maxwell tail formation	$5 \times 10^{-6}$	$5 \times 10^{-5}$
Ionization time constant	$2 \times 10^{-6}$	$8 \times 10^{-1}$
Electron energy transfer to molecules	$10^{-10}$	$5 \times 10^{-10}$
Electron heating of vibrational levels in molecules	$5 \times 10^{-6}$	$5 \times 10^{-5}$
Translational-vibrational relaxation	$10^{-7}$	$6 \times 10^{-7}$

### Chemi-ionization

Two types of mechanism have been suggested. In one type, electrons are produced as an end-product of a chain of chemical reactions. This mechanism is attractive since the conductivity depends directly on the electron density. The difficulty lies with the efficiency of the mechanism—electron densities in excess of  $10^{13}$ /c.c. are not normally produced by this process, and even at the exit of the duct one expects  $10^{13}$  electrons/c.c. by thermal ionization. The electron temperatures are kept close to the molecular temperature by the rapid transfer of energy to the molecular vibrational levels and under these conditions the recombination time constant (equal to the ionization time constant) will entail the process having to be repeated many times along the length of the duct. Moreover, the choice of fuel and oxidant will be determined by economic considerations, so there is not much room for using reactions particularly favourable to this process. If the process were used at all, it is clear that it would only be used to boost the ionization at the very end of the duct.

The other possible mechanism of chemi-ionization<sup>3</sup> is that the combustion process leaves the vibrational levels of the molecules in excited states. Because of the short time constant for energy transfer between the electrons and the molecular vibrational levels, the electron temperature is close to that of the molecular vibrations. With the resulting high electron temperature, ionization will begin to build up with the appropriate ionization time constant, but because of the short translational-vibrational relaxation time the process will have to be repeated many times along the duct to maintain the ionization, that is, there will have to be continuous combustion.

An upper estimate of the additional electron density can be obtained from the times in Table 1. Because of the short translational-vibrational relaxation time, the process will have to be repeated at least  $10^{-2}/6 \times 10^{-7}$  times or  $2 \times 10^4$  times. On each occasion only a fraction equal to the translational-vibrational relaxation time divided by the time for electron heating of the molecular vibrational states can go to the electrons, that is, a number less

Fig. 1

than 1/50. Hence, even assuming that all the combustion energy went into exciting molecular vibrations, less than  $10^{-6}$  of this would go into electron heating. Since each free electron takes 4 eV to ionize, the maximum electron density is  $10^{12}$  and the process is unimportant for magnetohydrodynamics.

#### External Source Ionization

The use of an external source (other than a radioactive one) to supply additional ionization implies the use of external power (for example, electricity) to cause ionization. It is therefore less efficient than the use of magnetohydrodynamic currents themselves to raise the electron temperature.

#### Magnetically Induced Ionization

The currents flowing in a magnetohydrodynamic generator are carried almost entirely by the most mobile particles—the electrons, and afterwards by energy transfer from the electrons to the gas molecules. The mean electron thermal energy can, therefore, in certain circum-

stances, be significantly greater than the gas temperature. The enhanced mean electron energy can be calculated as a function of Mach number of the gas flow and magnetic field strength<sup>4</sup>. Because of the strong energy coupling between electrons and molecules this process has been assumed to be inapplicable for molecular gases. However, Fig. 1 shows the results of detailed calculations using this method. The values of the fractional energy loss of an electron per collision as a function of electron energy have been taken from ref. 2. The values given in ref. 2 were obtained from experiments where the electron energy was many times greater than the gas molecules energy and the gas was at room temperature. In the portion of Fig. 1 where the electron energy is close to the gas temperature the amount of enhancement may, therefore, be considerably in error but will, however, cause little error in the electron energy. It is seen that a 40 per cent increase in electron energy may be obtained by working at velocities ( $U$ ), pressures ( $P$ ) and magnetic field strengths ( $B$ ):  $UB/P = 3 \times 10^4$ . This condition would be achieved by running the generator supersonically.

However, there are some doubts in interpreting the increased electron energy as an enhanced electron temperature and assuming the ionization and conductivity appropriate to equilibrium at the electron temperature. For example, it is not clear that the electrons will form a Maxwell distribution. Moreover, many of the ionizing collisions are caused by electron collision with excited seed particles, and the population of these excited states is likely to be determined by the molecular vibrational temperature rather than electron temperature.

Thus, although magnetically induced ionization would seem to be the most favourable of the enhanced conductivity possibilities, a realistic assessment of its potentialities must await the results of more detailed investigations. Both theoretical and experimental investigations are at present in progress.

The work was carried out at the Central Electricity Research Laboratories, and is published by permission of the Central Electricity Generating Board.

## ELECTRON SPIN RESONANCE SPECTRA OF POLYMETHYL METHACRYLATE AFTER EXPOSURE TO NITRIC OXIDE AND NITROGEN DIOXIDE

By DR. M. EBERT and DR. J. LAW

Paterson Laboratories, Christie Hospital and Holt Radium Institute, Manchester

IT was shown by Cook *et al.*<sup>1</sup> that nitric oxide (NO) reacted with powdered samples of polymethyl methacrylate (PMMA) to give free radicals with an asymmetric electron spin resonance signal. They suggested that this might result from a reaction between the gas and the doubly bound oxygen atom in the side arm of the monomer unit. The present article extends this work and shows that the signal arises from a reaction between the gas and traces of unreacted methyl methacrylate monomer (MMA) in the PMMA samples. It is also shown that nitrogen dioxide (NO<sub>2</sub>) has a similar effect.

Preliminary work was done using samples of unplasticized PMMA as used by Boag *et al.*<sup>2</sup> for dosimetry. For the main part of the work, purified samples of PMMA

were prepared from MMA in the following way. MMA monomer was first purified by washing with a solution of 20 per cent NaCl/5 per cent NaOH to remove inhibitors. It was then washed copiously with water to remove alkali, dried over anhydrous MgSO<sub>4</sub>, distilled under vacuum and stored in the dark at about 4° C. PMMA was then made from it by three different methods: (a) some monomer was de-aerated with oxygen-free nitrogen and irradiated with cobalt-60  $\gamma$ -rays for about 16 h at about 1,300 rads/min; (b) dry benzoyl peroxide was dissolved in purified MMA (0.1 per cent) and heated to 100° C until, after about 15 min, a syrup formed; the syrup was then heated at 60°–80° C overnight and for several hours at 100°–120° C; (c) 3 per cent PMMA,

Fig. 1. *a*, Electron spin resonance signal from PMMA after exposure to  $^{14}\text{NO}$  or  $^{14}\text{NO}_2$ . *b*, Weak component of signal *a*

0.007 per cent methacrylic acid and 0.05 per cent  $\alpha\alpha'$ -azodi-iso-butyronitrile were added to purified MMA. The mixture was heated for 30 h at  $40^\circ\text{C}$  and then for several hours at  $100^\circ\text{C}$ . The solids resulting from all three methods were then purified by dissolving in benzene (7:1,  $\text{C}_6\text{H}_6$  to polymer by weight) and reprecipitating in methanol at  $-30^\circ\text{C}$  (10:1,  $\text{CH}_3\text{OH}:\text{C}_6\text{H}_6$  by volume). The polymer was then dried in vacuum at  $100^\circ\text{C}$  for 24 h, and was further purified by repeating this procedure.

Samples of purified PMMA made by these three methods and also the unplasticized PMMA were filed or ground to a powder. The resulting particles were of the order of  $100\mu$  across or less. This size allows the gases to diffuse throughout the particles in times short compared with treatment times. These powders were then evacuated to pressures of the order of  $10^{-5}$  torr for several hours and then allowed to stand in contact with NO or  $\text{NO}_2$  for 24 h.

MMA was exposed to NO and  $\text{NO}_2$  in the following way. A few millilitres of MMA in a 50-ml. flask were de-aerated by freezing and thawing under vacuum and then allowed to stand under NO or  $\text{NO}_2$  for periods varying from 10

to 60 min. The liquid became noticeably blue but remained clear throughout. After this treatment it was frozen and the gas removed. Liquid samples were then condensed in tubes suitable for electron spin resonance measurements and sealed under vacuum, or transferred to other such tubes in air.

NO was obtained from cylinders supplied by Matheson and Co., Inc. The gas was purified by passing through KOH solution and two cold traps, one of solid carbon dioxide and a second of solid carbon dioxide and acetone mixture. The gas was then admitted to the PMMA samples, generally to atmospheric pressure.  $\text{NO}_2$  was prepared by heating  $\text{Pb}(\text{NO}_3)_2$ ; some oxygen is present in the mixture of  $\text{NO}_2$  and  $\text{N}_2\text{O}_4$ . Concentrations of  $\text{NO}_2$  quoted here refer to mixtures of  $\text{NO}_2$ ,  $\text{N}_2\text{O}_4$  and  $\text{O}_2$ .

A 50-ml. sample of  $^{15}\text{NO}$ , 99 per cent labelled, was obtained from 20th Century Electronics, Ltd. Small amounts of this were allowed to react with oxygen to form a mixture of  $\text{NO}_2$  and  $\text{O}_2$ . This mixture was in turn allowed to react with samples of PMMA and MMA as already described here.

Electron spin resonance spectra were recorded with a Hilger and Watts Microspin X-band (9,400 Mc/s) spectrometer, which uses 100-kc/s field modulation and gives first derivatives of absorption signals. In addition some Q-band (35,000 Mc/s) spectra were obtained from Hilger and Watts spectrometers in other laboratories, and are shown here as Fig. 6.

Fig. 2. *a*, Electron spin resonance signal from MMA after exposure to  $^{14}\text{NO}$  or  $^{14}\text{NO}_2$ . *b*, Separate lines of signal in *a*

Fig. 3. Electron spin resonance signal from MMA after exposure to  $^{15}\text{NO}_2$  and subsequent freezing

All electron spin resonance measurements were made in 'Pyrex' tubes, 6 mm outer diam. and 5 mm internal diam. Any signal from the glass was negligible at the spectrometer sensitivities used.  $g$  values were estimated assuming the  $g$  value for diphenyl-picryl-hydrazyl = 2.0036.

Samples of PMMA powder showed no electron spin resonance signal before exposure to NO or  $\text{NO}_2$ , except that for a few minutes immediately after filing a very weak asymmetric signal could be detected which looked like that normally attributed to peroxy radicals  $\text{ROO}\cdot$  (ref. 3).

When powdered samples of unplasticized PMMA were exposed to NO at atmospheric pressure for 24 h, the signal shown in Fig. 1a was found, as described by Cook *et al.*<sup>1</sup>. The  $g$  values of its principal features are given in Table 1 where the uncertainties quoted are standard deviations of means. This is a mixture of two asymmetric signals, but one is very much weaker than the other. The latter is shown in Fig. 1b and is probably responsible for the small peak at B in Fig. 1a.

It was found that when PMMA was allowed to stand with excess NO, only a limited amount of gas was taken up, after which the PMMA appeared to be saturated. By weighing the PMMA before and after treatment, it was estimated that if the gas reacted with the polymer it only reacted with about 1 in 50 monomer units. Measurement of the volume of gas taken up gave an estimate of 1 in 20 monomer units.

A pressure of 1.5 cm mercury of  $\text{NO}_2$  was found to give a strong signal identical with that of Fig. 1a which was stable for a few weeks. If  $\text{NO}_2$  was used at atmospheric pressure a very weak signal of this kind was observed for about 1 h afterwards, but then disappeared.

This signal, whether produced by NO or  $\text{NO}_2$ , is stable for periods of months in either air or vacuum. It is also stable in the presence of NO for a few weeks at least, but decays in the presence of  $\text{NO}_2$ . It is unaffected by radiation at doses of at least  $10^7$  rads. Samples of unplasticized PMMA which were treated with NO or  $\text{NO}_2$  for 24 h and then re-evacuated and irradiated showed no trace of the well-known 5-plus-4 line electron spin resonance signal normally found when PMMA is irradiated *in vacuo*.

When samples of purified PMMA made by each of the three methods described here were exposed to either NO or  $\text{NO}_2$ , no electron spin resonance signal could be detected. In contrast to this, when MMA was first condensed on to these powders under vacuum, and the powders then exposed to either gas, the electron spin resonance signal of

Table 2

Signal from:	$g$ Value	Hyperfine splitting	Line widths
MMA and $^{14}\text{NO}$	2.0065 $\pm 0.0001$	$28.2 \pm 0.2$ gauss	$0.9 \pm 0.1$ gauss
MMA and $^{15}\text{NO}$	2.0065 $\pm 0.0001$	$20.0 \pm 0.2$ gauss	$1.0 \pm 0.1$ gauss

Fig. 1a was obtained from each of the three samples as with the unplasticized PMMA. A further sample of PMMA, made by irradiating MMA but without subsequent removal of unreacted MMA, also gave this signal. When monomer was condensed on to silica gel as an inert solid matrix, the silica gel showed the electron spin resonance signals of Fig. 1a after exposure to NO or  $\text{NO}_2$ , whereas silica gel alone exposed to these gases shows no electron spin resonance signal.

MMA exposed to NO or  $\text{NO}_2$  turned blue and gave an electron spin resonance signal of three lines equally spaced but appearing slightly unequal in strength in first derivative recordings, and of slightly different shape. This signal is shown in Fig. 2a and the three lines separately in Fig. 2b. It was provisionally attributed to an unpaired electron closely coupled to the nitrogen-14 atom which has spin quantum No. 1. A slight splitting can be seen in each line, presumably due to weak interaction with protons. The  $g$  value, hyperfine splitting and line width are given in Table 2.

Fig. 4. a, Electron spin resonance signal from PMMA after exposure to  $^{15}\text{NO}$  or  $^{15}\text{NO}_2$ . b, Weak component of signal a.

A sample of MMA treated with  $\text{NO}_2$  and then cooled in liquid nitrogen gave an electron spin resonance signal when frozen as shown in Fig. 3. Only a relatively small sample could be accommodated under these conditions and the signal was correspondingly weak, but after allowing for the zero line drift it is the same signal as in Fig. 1a to well within the noise-level. The presence or absence of the signal of Fig. 1b could not be established. Untreated MMA gave no signal when frozen.

When powdered PMMA containing MMA was exposed to  $^{15}\text{NO}_2$  an electron spin resonance signal was obtained which is shown in Fig. 4a. Its  $g$  values are given in Table 1. This was also found to consist of two asymmetric signals, one very much weaker than the other, and the latter is shown in Fig. 4b. MMA was also exposed to  $^{15}\text{NO}_2$  and a doublet electron spin resonance signal was obtained (Fig. 5) as expected since nitrogen-15 has spin quantum number  $\frac{1}{2}$ . The hyperfine splitting and line width are given in Table 2. The hyperfine splitting is less than for the triplet signal, and the ratio of the splittings is equal to that of the nitrogen-14 and nitrogen-15 magnetic moments to within the limits of experimental error.

Electron spin resonance spectra from samples of PMMA exposed to  $^{14}\text{NO}_2$  and  $^{15}\text{NO}_2$  were also obtained at Q band frequencies. These are shown in Fig. 6. The  $g$  values of their principal features are listed in Table 1, and are unlikely to be in error by more than  $\pm 0.001$ .

Since the signals obtained from PMMA after exposure to NO or  $\text{NO}_2$  remain at the same intensity when these gases are removed, it seems likely that they result from a chemical reaction with some constituent of the polymer, rather than from gas molecules being trapped in some way in the solid. PMMA made by three different polymerization processes and purified to remove MMA does not give the electron spin resonance signal of Fig. 1a after exposure to NO or  $\text{NO}_2$ . If small amounts of MMA are present, however, samples of PMMA do show this signal whatever their mode of polymerization. This strongly suggests that the signal arises from an interaction between the gas and MMA, and does not depend on the groups which initiate the polymer chains. Furthermore, small amounts of purified MMA when condensed in silica gel as an inert solid matrix show this signal after exposure to either gas, and the same signal is obtained when purified MMA is exposed to these gases and then frozen. These results provide further support for the conclusion that the signal is given by the products of a reaction or reactions between NO or  $\text{NO}_2$  and MMA. This is qualitatively consistent with the observed uptake of NO by unplasticized PMMA. The possibility that low molecular weight polymer is involved cannot be excluded.

The most probable site at which the gases might react with MMA is the double bond between the carbon atoms, but this has not been confirmed. It seems certain, however, that the radical includes the nitrogen atom. After MMA has been exposed to either  $^{14}\text{NO}$  or  $^{14}\text{NO}_2$  it gave a triplet electron spin resonance signal which was attributed to an unpaired electron interacting with the nitrogen-14 atom. If the MMA was then frozen this triplet was trans-

Fig. 5. Electron spin resonance signal from MMA after exposure to  $^{15}\text{NO}$  or  $^{15}\text{NO}_2$ .

Fig. 6. Q-band electron spin resonance signal from PMMA after exposure to: a,  $^{14}\text{NO}$  or  $^{14}\text{NO}_2$ ; b,  $^{15}\text{NO}$  or  $^{15}\text{NO}_2$ .

formed to a signal like that of Fig. 1a, and returned to its original form on melting. This implies that the signal of Fig. 1a also arises from the nitrogen-14 atom. This conclusion is confirmed by the experiments with  $^{15}\text{NO}$  and  $^{15}\text{NO}_2$  in which MMA showed a doublet signal and PMMA showed a signal quite different from Fig. 1a, as seen in Fig. 4.

Several discussions took place with Dr. P. D. Cook and Mr. V. J. McBrierty of Middlesex Hospital Medical School who were working independently on a related topic [see p. 1197 of this issue of *Nature*].

We thank Dr. A. J. Swallow of this laboratory, and Dr. L. H. Sutcliffe of the University of Liverpool, for advice on the preparation and purification of PMMA samples and on other matters. We also thank Mr. H. M. Assenheim and the staff of Hilger and Watts Ltd., Dr. J. C. Evans of University College, Cardiff, and Prof. D. J. E. Ingram and Mr. S. D. Lacey of the University of Keele for help in providing the spectra shown in Figs. 6a and b and their corresponding  $g$  values.

## LETTERS TO THE EDITOR

## ASTROPHYSICS

Origin of the  $C(A^3\Pi_g) \rightarrow C_2(X^3\Pi_u)$  Emission in Comets

THE observation of the  $C_2$  Swan bands ( $A^3\Pi_g \rightarrow X^3\Pi_u$ ) in emission in the coma of comets was at one time taken as evidence that the ground state of  $C_2$  was the  $X^3\Pi_u$  state since this cometary emission is known to arise by means of a fluorescence process. However, Ballik and Ramsay<sup>1</sup> have shown that the ground state of  $C_2$  is  $x^1\Sigma^+_g$  and consequently the observation of the Swan bands would be consistent with the following: (1)  $C_2$  is formed initially in the triplet system by decomposition (probably photodecomposition) of a hydrocarbon molecule. (2) The  $^3\Pi_u \rightarrow ^1\Sigma^+_g$  transition does not occur to an appreciable extent prior to fluorescence excitation by solar radiation or in the time between successive excitations. The latter implies that  $C_2$  experiences an insufficient number of collisions, or possibly no collisions, to effect the forbidden  $^3\Pi_u \rightarrow ^1\Sigma^+_g$  transition. This is not an unreasonable requirement since it is known that the rotational and vibrational distribution of  $C_2$  in cometary atmosphere corresponds to a temperature of about 2,500° K and that  $C_2$ , therefore, must experience few if any collisions between the time of its formation near the nucleus and the time of its excitation farther out in the coma.

Thus, while the second requirement seems to be met, the first requirement of the specific formation of  $C_2$  in the triplet system on photodissociation of a hydrocarbon molecule needs to be demonstrated. Any significant formation of  $C_2$  in the singlet system must be excluded since appreciable concentrations of  $C_2$  in the  $x^1\Sigma^+_g$  ground state would eventually lead to population of upper singlet states ( $b^1\Pi_u$ ,  $c^1\Pi_g$ ,  $d^1\Sigma^+_u$ ) and emission from these states (Fig. 1).

Recent work in our laboratory on the vacuum ultra-violet photolysis of  $CH_4$ ,  $C_2H_2$ ,  $C_2H_4$ , and  $C_2H_6$  suggests that photodissociation of methane and acetylene in the

vacuum ultra-violet at low pressures leads to the formation of  $C_2$  in the  $^3\Pi_g$  state. The emission from  $CH_4$  was very weak and, since a secondary process for  $C_2$  production from methane is required, the more interesting  $C_2H_2$  system was investigated in detail. A weak emission consistent with the Swan bands of  $C_2$  and the detection of molecular hydrogen formation was explained in terms of the decomposition of an electronically excited acetylene molecule<sup>2</sup>.

Emission in the regions of other  $C_2$  transitions (Fig. 1) was not observed. No emissions were observed from  $C_2H_4$  and  $C_2H_6$ .

On this basis we would suggest that the origin of the  $C_2$  Swan bands in cometary emission spectra is the photodissociation of acetylene or an acetylene-type molecule leading to an eventual accumulation of  $C_2$  in the  $X^3\Pi_u$  state.

## PHYSICS

## A Nitrogen-14 Triplet and Nitrogen-15 Doublet as a Standard for Electron Spin Resonance Hyperfine Splitting Determinations

THE results given here follow on from an earlier communication in which it was reported that treatment of certain methacrylate polymers with nitric oxide gas induced an electron spin resonance signal<sup>1</sup>. It was later found that pure polymethyl methacrylate powder did not give a signal on treatment, and Law and Ebert<sup>2</sup> have suggested that the observed signal was due to traces of monomer in the polymer sample.

Methyl and *n*-butyl methacrylate monomers were treated with nitric oxide either by allowing the sample to stand in the presence of the gas for about an hour or, alternatively, by bubbling the gas through the monomer, the latter method being found to be the more satisfactory. The observed electron spin resonance absorption was investigated in the X-band region and the first derivative of the resulting signal (shown in Fig. 1) was found to consist of three evenly spaced peaks of equal intensities. It is suggested that the nitric oxide reacts with the carbon double bond ( $C=C$ ) and as a result of this both an unpaired electron and a nitrogen nucleus become associated with the monomer. Similar results were obtained with nitrogen dioxide.

The *g*-value of the central peak was compared with that of diphenyl picryl hydrazyl (2-0036) and was found to be

Fig. 1. Energy-level diagram of  $C_2$

Fig. 1

Fig. 2

$2.0058 \pm 0.0007$ . The splitting between adjacent peaks was  $14 \pm 0.5$  gauss corresponding to 39 Mc/s. The fine structure of the signal is interpreted as resulting from an interaction between the unpaired electron and the nitrogen ( $^{14}\text{N}$ ) nucleus.

The results of a further experiment support this interpretation. The interaction of an unpaired electron with a nucleus of spin  $I$  gives rise to  $(2I + 1)$  peaks. In the case of  $^{14}\text{N}$  spin  $I = 1$ . The isotope  $^{15}\text{N}$  (spin  $I = \frac{1}{2}$ ) was substituted for  $^{14}\text{N}$  in the nitric oxide gas in which case a doublet was obtained (Fig. 2). The doublet splitting was  $20.3 \pm 0.5$  gauss corresponding to 57 Mc/s. A mixture of two monomer samples treated separately with  $^{14}\text{NO}$  and  $^{15}\text{NO}$  gave a simple superposition of the triplet and doublet signals with both signals symmetrical about the central triplet peak. Assuming that the electronic wave function of the unpaired electron is the same at the site of the  $^{14}\text{N}$  and  $^{15}\text{N}$  nuclei, the results are in agreement with Fermi's hyperfine interaction theory<sup>3</sup>, that is, the ratio of the doublet and triplet splittings is equal to the ratio of the  $^{14}\text{N}$  and  $^{15}\text{N}$  nuclear magnetic moments, within the measured accuracy.

Comparison of the  $^{14}\text{N}$  triplet in nitric oxide-treated monomer and in peroxalimine disulphonate solution<sup>4</sup> has shown the former to be more stable at room temperature (there was no appreciable decay over a period of a month for a sample sealed in vacuum) and with a lower dielectric loss at X-band frequency. A sample was diluted with untreated monomer and the amplitude of the first derivative signal was found to decrease linearly with monomer dilution while the splittings remained constant to within the stated accuracy. It is therefore suggested that this sample would be more suitable for use in electron spin resonance line splitting determinations.

Measurement of the hyperfine splitting at very high frequency and zero field is being carried out, and the results will be reported in the near future.

This work was carried out independently of the work reported on related topics by Law and Ebert, although the two groups have kept in close liaison [see p. 1193 of this issue of *Nature*].

### Some Applications of an Improved Scanning Electron Diffraction System

An improved system for scanning electron diffraction has recently been developed in this laboratory. The main improvements on the earlier system of Grigson<sup>1,2</sup> are greater stability and sensitivity of the diffraction instrument and a more accurate display; moreover, provision is made for evaporating specimens, so that intensity profiles from a growing film are obtained; and the diffraction patterns may be scanned in two dimensions.

These improvements considerably extend the usefulness of direct-recording electron diffraction for examination of thin films: (1) The abscissae of the peaks of the intensity profiles, as measured from the recordings, are proportional to  $\sqrt{E} h^2$  to an accuracy of 0.2 per cent over the range of

Fig. 1

Fig. 2

Fig. 3

Fig. 4

scattering angles  $0 < \beta < 0.2$  radians, thus  $d$ -spacings corresponding with unknown impurities in the films must be correct to this accuracy.

(2) The high sensitivity enables weak impurity rings close to strong rings from the principal constituents of the films to be easily shown: for example, a ring of 1 per cent of the intensity of an adjacent ring, with an angular deviation of 1 milliradian away, can be clearly displayed (Fig. 1).

(3) Films may be grown<sup>3</sup> and successive diffracted intensity profiles then correspond with uniform average-thickness increments in the film. Sensitivity is sufficient to give clear signals from increments of average thickness equal to about a monolayer of atoms; see Fig. 2, which shows the growth of an 80/20 nickel-iron film.

Such increments may be observed whether the growing layers are amorphous<sup>3</sup>, or consist of crystals of very small or relatively large lateral dimensions. Thus the presence or development of small inclusions of crystalline impurity can be detected. The values of the thickness increments are obtained from interferometry and from use of a growth rate monitor<sup>4</sup>.

(4) Debye-Scherrer patterns scanned in two dimensions may be obtained. Fig. 3 is such a pattern from an iron film about 400 Å thick, inclined to the electron beam. The variation of intensity due to preferred orientation is vividly shown.

(5) Patterns from single crystal films may be displayed. Fig. 4 shows the intensities from a gold single crystal

film about 200 Å thick. Signal-levels are now about two orders greater than with powder patterns. An interesting feature is that the amount of background between the diffracted rays is high and comparable with that from polycrystalline films of similar thickness.

### Relative Velocity in Relativity Theory

CONSIDER three co-ordinate systems,  $S$ ,  $S'$ , and  $S''$ . Let the velocities of the origins of  $S'$  and  $S''$ , as observed in  $S$ , be  $Sv_{S'}$  and  $Sv_{S''}$ , respectively, and let the velocity of  $S''$ , as observed in  $S'$ , be  $S'v_{S''}$ . Then the remaining possible velocity observations give  $S'v_S = -Sv_{S'}$ ,  $S''v_S = -Sv_{S''}$ , and  $S''v_{S'} = -S'v_{S''}$ . In principle, these six velocities can be measured directly (which is what we mean by the words 'as observed in'). If we wish to use the Lorentz transformation equations to express relations, valid in one co-ordinate system, in terms of another of these co-ordinate systems, then the appropriate one of the foregoing velocities appears in the transformation equations.

It is possible for an observer in  $S$  to measure that the velocity of  $S'$  is  $Sv_{S'}$ , and that of  $S''$  is  $Sv_{S''}$ , and so to say that the relative velocity of  $S''$  with respect to  $S'$  is  $Sv_{S''} - Sv_{S'}$ . This is not at all the same as the velocity  $S'v_{S''}$ , because the co-ordinate systems in which these quantities are measured are different, as is indicated explicitly by the left superscripts used in the present notation. Therefore, it is in principle quite invalid for the relative velocity  $Sv_{S''} - Sv_{S'}$  to be put into the Lorentz equations for transformations between  $S'$  and  $S''$ .

However, in certain specific cases it is permissible to use the relativistic velocity transformation equation:

$$S'v_{S''} = \frac{Sv_{S''} - Sv_{S'}}{1 - \frac{Sv_{S''} Sv_{S'}}{c^2}} \quad (1)$$

(or its vector generalization when the velocities are not parallel) to get the required velocity  $S'v_{S''}$  in terms of the relative velocity  $Sv_{S''} - Sv_{S'}$ . This equation is valid for transformation between inertial systems, where the velocities are uniform, and is derived for this case.

An example where equation (1) cannot be used is given by the Mössbauer experiment of Champeney and Moon<sup>1</sup>, in which source and absorber were placed at opposite points on the periphery of a uniformly rotating rotor. Let  $S$  be a laboratory system of co-ordinates,  $S'$  a system in which the Mössbauer source is at rest and  $S''$  a system in which the Mössbauer absorber is at rest. An observer in  $S$  (the laboratory) notes that  $Sv_{S''} = -Sv_{S'} = v$ , and so deduces that the relative velocity of  $S''$  and  $S'$ , observed in  $S$ , is  $Sv_{S''} - Sv_{S'} = 2v$ .

However, it is obvious that in the co-ordinate system  $S''$  (absorber), the system  $S'$  (source) is seen to be stationary, so that the velocity of the source as seen by the absorber is  $S''v_{S'} = 0$ , which is not deducible from equation (1). This conclusion is confirmed by the null result of the experiment, in which  $S''$  (that is, the absorber itself) observed no Doppler shift of the source frequency for the conditions stated (source and absorber at same pseudo-gravitational potential). We ascribe the inapplicability of equation (1) for this case to the fact that the transformation relations between  $S'$  and  $S''$  are inhomogeneous consequent on  $S'$  and  $S''$  being non-inertial systems.

Thus, Champeney and Moon's experiment does not indicate that 'the special theory is wrong', as claimed by Essen<sup>2</sup>.

It is perhaps of interest to note that interpretation of Champeney and Moon's experiment need not be dependent on special relativity. Time dilatation in a uniformly rotating co-ordinate system may be deduced if we believe that clocks in such a system can be synchronized by using the postulate of the constancy of the velocity of light. In the rotating system, if a light ray travels a go-and-return path  $2 dr$  in time  $2 d\tau$ , we have:

$$(d\tau)^2 = \frac{(dr)^2}{c^2} \quad (2)$$

while for the same events observed in a stationary system, each path length is  $[(dr)^2 + (r d\phi)^2]^{\frac{1}{2}} = [(dr)^2 + (r\omega dt)^2]^{\frac{1}{2}}$ , so that:

$$(dt)^2 = \frac{(dr)^2}{c^2 - \omega^2 r^2} \quad (3)$$

whence:

$$d\tau = \left(1 - \frac{\omega^2 r^2}{c^2}\right)^{\frac{1}{2}} dt \quad (4)$$

the same result as given by special relativity for  $v = \omega r$ .  
D. W. POSENER

C.S.I.R.O.

Division of Applied Physics,  
Chippendale, New South Wales.

<sup>1</sup> Champeney, D. C., and Moon, P. B., *Proc. Phys. Soc.*, **77**, 350 (1961).

<sup>2</sup> Essen, L., *Nature*, **202**, 787 (1964).

It is questionable whether the Lorentz transformations should be applied to any of the experiments under discussion, since accelerations are involved. If they are,  $S$ ,  $S'$  and  $S''$  in D. W. Posener's letter must be regarded as inertial systems and  $S'$  is then moving with the velocity  $2v$  relative to  $S''$ . According to the special theory the transformation can then be applied between any pair of the systems and it is impossible to differentiate between them.

Equation (4) of Posener's letter does not agree with Einstein's result,  $d\tau$  and  $dt$  being interchanged, although in both cases  $d\tau$  applies to the moving system and  $dt$  to the stationary system. The explanation arises from the inadequate definition of the symbols used in relativity theory. There are actually four measurable times, and if suffixes are used to distinguish them they are by postulate related as follows:

$$d\tau_1 = dt_2, d\tau_2 = dt_1$$

Einstein uses one pair and Posener the other, and both forms of the equation are equally correct. It was this inadequate definition of the symbols which gave rise to the 'paradox' prediction in which the relativity effect was assumed to exist between  $d\tau_1$  and  $dt_2$ .

### Factors affecting Energy Resolution in Liquid Scintillation Counting

WHEN using  $\beta$ -conversion electron peaks to calibrate a liquid scintillation  $\beta$ -spectrometer, a number of factors which affect energy resolution must be borne in mind.

Care must be taken in selecting the photomultiplier tube, and in our case we chose an E.M.I. No. 6097 F tube. We used a silicone 30,000 centistoke grease to ensure good optical coupling between the vial containing the liquid scintillator and the phototube, and took care that air bubbles were eliminated. We found that the best results were obtained when the vial was dipped into silicone

grease, thus providing an optical coupling about 1 mm in thickness. (Systems in which the vial is separated from the phototube by an air gap do not give sufficient resolution to define the conversion electron peaks, even when this gap is very small.)

The purity of the solution is of great importance. The presence of water is of great consequence, and even if only 0.1 ml. of an aqueous solution of the isotope to be counted is added to 10 ml. of dioxane containing a liquid scintillator, the resolution is reduced to nil. We found that this difficulty could be overcome by either: (a) careful evaporation of the aqueous solution to dryness in the vial before adding the scintillator; or (b) by complexing the dry material with an organic solvent which could be mixed with the scintillator, but which does not quench the scintillation process—for this purpose di-2 ethylhexyl orthophosphoric acid was successfully used for the rare earths and tetraphenylborate in amyl acetate for caesium-137. Not all the active material, however, was complexed by this method, so the extracted portion was transferred to another vial. This technique gave better results than (a).

It is essential that the composition of the liquid scintillator should be kept as simple as possible, in order to avoid multiple-energy transfers which might reduce the resolution. The mixture xylene-PPO (2,5-diphenyloxazole) gave better resolution than xylene-PPO-POPOP (2,2-p-phenylenebis(5-phenyloxazole)) and without loss of efficiency. It is clear that there is more than one possibility of energy transfer in the case of xylene-PPO-POPOP: that is, either xylene to PPO or xylene to POPOP—both of which give a different output of light, or xylene to PPO, followed by transference of a part of its energy to POPOP, some of the energy being emitted directly in the form of light.

Finally, we found that for the best results the vial should be transparent and surrounded by a reflecting material—in our case 'Teflon' was used.

Under these conditions, the 0.625-MeV conversion electron peak of  $^{137}\text{mBa}$  for calibration of the  $\beta$ -spectrometer gave a resolution of 25 per cent.

## GEOCHEMISTRY

### Interpretation of Micro-structures in Carbonaceous Meteorites

In their recent article<sup>1</sup>, Claus and Suba-C reiterate a number of older arguments in favour of a biogenic origin of the non-birefringent, globular objects in the Orgueil meteorite. I am of the opinion that these are microchondri of glass and I have previously expounded my arguments in favour of this<sup>2</sup>.

In their new arguments for a biogenic origin for the structures, Claus and Suba-C commented that the histograms of these colourless globules show three maxima which seem to correspond to three distinct species of the hypothetical organisms. It appears that they did not see the histogram of similar objects from the same meteorite contained in my paper<sup>3</sup>, which is practically a replica of theirs. This similarity between the two histograms indicates that the size distribution of the structures in question must be remarkably uniform throughout the

meteorite, since my histogram was constructed from a different sample.

In the course of preparing my histogram, however, I noted that the size-distribution pattern of the magnetite globules, which are present in approximately double the number of the transparent globules, is exactly the same as that of the transparent globules (see Fig. 8, ref. 3). To the best of my knowledge, none of the proponents of the biogenic origin of the transparent globules attributed a similar origin to the opaque magnetite globules. However, we are forced to conclude that the agency that caused the sorting of the opaque magnetite globules must also have been responsible for the sorting of the transparent globules.

I suggest that the globules in question represent fine solidified spray particles which were ejected by gases from the interior of the parent body and gradually became arrested and sorted in the course of the gases permeating the hydrated silicate-carbonaceous phase, close-to-surface cosmic dust—through gravitational factors and the effects of random collisions with other spray particles and cosmic dust particles.

The characteristic form of the histograms with their 2–3 maxima can be explained by assuming that several gusts of gas traversed the cosmic dust at different epochs: the relatively faster gusts transported, as a rule, coarser matter and therefore produced a maximum at a higher diameter, while the slower blow-outs were responsible for the maxima at smaller diameters.

The third point which I discussed in my paper was the fact that the proportion of single crystals of olivine (olivine microchondri) increases as the diameter of the globules increases. This will be realized when we consider that with greater diameter the probability of nucleation of olivine in the glass of close-to-olivine composition progressively increases.

G. MUELLER

Birkbeck College,  
University of London.

<sup>1</sup> Claus, G., and Suba-C., E. A., *Nature*, **204**, 118 (1964).

<sup>2</sup> Mueller, G., *Nature*, **196**, 929 (1962).

<sup>3</sup> Mueller, G., in *Advances in Organic Geochemistry. Proc. Intern. Meeting*, Milan, 1962, 114 (Pergamon Press, London and New York, 1963).

In our recent article<sup>1</sup>, a size distribution histogram of 303 randomly selected type 1 and 2 organized elements was presented and the results were interpreted as possibly indicating a biogenic origin for these elements. Prof. Mueller in his note reiterates his older argument in favour of an abiogenical origin of these structures and suggests that the particles arose through the solidification of fine sprays and were ejected by gases from the interior of the parent body of the meteorite. He refers to his histogram, which, according to him, is practically identical to the one we presented. Several points, however, speak against the acceptability of the identity of the histograms. Since one of us (G. Claus) was a participant at the first International Meeting in Organic Geochemistry in Milan, 1962 (Prof. Mueller<sup>2</sup> mentions our presence in his paper, p. 118), naturally we are well aware of Prof. Mueller's results; however, even at that Meeting, during the discussion, it was pointed out that a basic misunderstanding exists over the identification of what Prof. Mueller calls glass particles or olivine crystals and what we call type 1 or 2 organized elements. In his histogram (*loc. cit.*, p. 114), the curve indicated as glass and homologized with the organized elements is clearly not identical with the histogram we presented. Indeed, the organized elements are never 'transparent globules', as stated by Mueller, and are definitely not composed of glass. This has been demonstrated by the electron microprobe (Nagy *et al.*<sup>3</sup>); most of, and probably all, the type 1 and 2 organized elements are structures which possibly contain limonite. It is

possible that Prof. Mueller may have missed this article and, similarly, the subsequent work on the properties of the organized elements, for example, that of Urey<sup>4</sup> in which it is stated that after acid treatment of the meteorite an acid-insoluble residue is obtained which is composed primarily of spherical bodies. The large number and size of these bodies show good correlation with the numbers and shapes of organized elements in native meteorite preparations. Mueller does not make any allusion to this finding; furthermore, he does not take into account the work of Nagy *et al.*<sup>5</sup> concerning the ultra-micro ultra-violet absorption spectra derived from single organized elements, which indicate the possible presence of proteinaceous and nucleic acid-like substances in them. Clearly these data definitely contradict his assumption about the glassy nature of the organized elements. It seems that we are dealing with a quite different group of particles from that which Prof. Mueller counted.

So far as the size distribution of the olivine crystals is concerned there is no correlation whatsoever between Prof. Mueller's histogram (*loc. cit.*) and our data.

The size distribution of the magnetite particles is interesting. However, it is not at all clear from Prof. Mueller's data whether he considered in his histogram only the really globular forms, which are rather rare, or if all kinds of magnetic 'globules' were represented. Should the latter be the case, it is easy to understand the size-distribution diagram which he presents. In an earlier paper (Nagy *et al.*<sup>5</sup>) we pointed out the differences which exist between the sizes and shapes of the magnetic particles. According to further investigations which we have carried out (unpublished results) these particles, even if one strictly separates the completely globular forms, do not show a uniform size distribution. On the other hand, if all kinds of magnetic particles are carefully measured and the elongated or more or less shapeless forms are also included, dependent on whether their longest or shortest measurement is taken, it is possible to construct histograms which have 2, 3, 4, 6 or even 8 peaks. This is just a question as to which measurements the investigator is inclined to use in constructing these curves.

The number of magnetite particles was reported by us (Nagy *et al.*<sup>6</sup>) to be approximately 7,000/mg of the meteorites belonging to Wilk's<sup>7</sup> type 1 carbonaceous chondrites. Prof. Mueller<sup>1</sup> gives a count which is approximately double the number of the organized elements. As the number of organized elements in 1 mg of meteorite is approximately 1,500, the number of the magnetic particles would be 3,000 according to Mueller. There is definitely a discrepancy between these two numbers, which again does not help to identify the granules that Mueller calls magnetite and represents in his histogram. The number of unquestionably spherical magnetite granules is only about one-seventh to one-eighth of the total number—again a much smaller number than would account for the number of magnetite granules possibly represented by Mueller.

## GEOLOGY

## Age of the Caledonian Orogeny and Metamorphism in Britain

RECENTLY a hypothesis on the age of the main orogenic deformation of the Dalradian rocks of Britain proposed by Fitch, Miller and Brown<sup>1</sup> was criticized on stratigraphic grounds by T. G. Miller<sup>2</sup>. I find myself in agreement with the essentials (though not the whole) of Miller's argument against a Pre-Cambrian age for the main orogenic deformation of the Dalradian rocks, and feel that some further points should be made on this aspect of the 'working hypothesis' of Fitch, Miller and Brown. A fuller account of my views on the geographical and time relationships of the 'early Caledonian' and 'late Caledonian' orogenies of Britain is being prepared to amplify the conclusions briefly indicated in the introduction of an earlier work<sup>3</sup>, but it would appear pertinent to raise briefly some of the relevant points now.

In their original article and in their later reply<sup>4</sup> to T. G. Miller the three authors reject the only published accounts<sup>5,6</sup> of detailed investigations of the Leny Limestone of Callander since the discovery by Pringle of Middle Cambrian trilobites there<sup>7</sup>. The interpretation of isotopic data by Fitch, Miller and Brown does not appear to be sufficiently unequivocal to allow the rejection of Stone's conclusion that the Leny Limestone forms an integral part of the Dalradian succession without re-mapping of the Callander area to find another structural hypothesis in agreement with the field evidence. At present the evidence of stratigraphic and structural relationships as they appear in the Callander area must be given more weight than isotopic data which are manifestly open to more than one interpretation<sup>1,8,9</sup>. Moreover, although fossils have so far been found only at this one locality, it seems to me (as it did to Anderson<sup>5</sup> and Shackleton<sup>10</sup>) highly suggestive that the Leny Grits of Arran are divided by a thin group of slates with a limestone in their middle, giving a stratigraphic succession closely similar to that advocated for the Callander area. In Arran these strata occur only a little lower in the exposed succession than the 'Arenig' rocks of the North Glen Sannox area. The advocated Arenig age of these rocks now seems uncertain in view of the evidence suggestive of Pre-Arenig folding and metamorphism in north-west Ireland and since their assignment to the Arenig was based on a lithological comparison of common rock-types and the presence of two poor specimens of a brachiopod genus which can be found in both Cambrian and Ordovician rocks. Nevertheless, whether these rocks be of Cambrian or Arenig age, it would seem relevant that they appear to have shared completely in the folding and metamorphism of the Dalradian rocks, from which they are separated by only a possible slight disconformity<sup>11</sup>; it would appear that here, as in the Callander area, the highest strata involved in the orogenic deformation contain Lower Palaeozoic fossils.

The suggestion by Fitch, Miller and Brown that the  $F_3$  phase of the Highlands may be equivalent to the  $F_1$  of Wales, Isle of Man, Lake District, etc., appears, in the present state of knowledge, attractive, but their brief quotation, without any details, of Pre-Devonian fold amplitudes of 10,000–15,000 ft. in the Midland Valley of Scotland<sup>12</sup> as supporting this link tends to obscure the true geographical relationships. It may be mentioned in passing that the concept of fold-amplitudes as defining orogeny is itself open to criticism, since the essential characteristic of orogeny is horizontal crustal shortening rather than differential vertical movement, though in the cases quoted orogenic deformation is not disputed. The main point here is that both the localities mentioned as examples of end-Silurian folding are right against the southern margin of the Midland Valley. A little farther north in the Lesmahagow district, the Hagshaw Hills and the Tinto area, and much farther north at Stonehaven,

the Silurian rocks remained horizontal and undisturbed until Middle Devonian times. It appears probable that the major part of the Midland Valley remained a stable block separating fold movements in the country to the south from possibly synchronous events in parts, in any event, of the mobile belt to the north.

The sudden nature of the boundary of this block to the south of the Hagshaw Hills and Tinto may be in part due to differences in the stratigraphic/structural level of the deformed and undeformed rocks, the marginal folds of the orogeny fading out upwards as well as laterally. Making allowance for this, however, the edge of the end-Silurian orogenic belt in southern Scotland (also apparently in eastern Wales between Welshpool and Long Mountain) was far more sudden than the available exposures would require for the southern limit of an early Palaeozoic orogeny of the Dalradian rocks of the British Isles. On this basis, and also on account of other examples of knife-edged orogenic belts in other parts of the world (as in Algeria and parts of the eastern Rockies), there appears no validity in Fitch, Miller and Brown's contention that an early Palaeozoic age for the main deformation of the Dalradian rocks is unlikely due to the absence of movements at these times in areas farther south.

In summary, while it is agreed that there is room for more work on the rocks of the southern strip of the Highlands, at present there appears reasonable evidence that strata containing Palaeozoic fossils were involved in the main phases of deformation of the Dalradian. There seems no reason to refute this evidence because the age-dates of the main orogenic movements have been largely obscured by later events, when all the ages found in the Dalradian rocks could as well result from modification of an early Palaeozoic orogeny as from partial changes of original Pre-Cambrian dates.

## Coesite from Lake Mien, Southern Sweden

LAKE MIEN (lat. 56° 25' N, long. 14° 52' E.) is situated about 30 km north of Karlshamn, or almost on the border between the provinces of Smaland and Blekinge. The depression in which the lake is located is to a large extent filled by glacial deposits from the last glaciation. No outcrops have been found around the lake, except a few on the northern shore, which consist of granite.

During the regional mapping of Sweden, Holst<sup>1</sup> discovered that boulders of peculiar rocks, regarded by him as volcanic, occurred within an area south of the lake. Such boulders are common both in the till and in the glacial sediments. It is evident that they derive from the bottom of the lake. This geological structure is regarded in all books on the regional geology of Sweden even the most recent ones<sup>2,3</sup>, as the remnants of a young rhyolitic volcano, probably Tertiary.

A survey of the literature shows that another interpretation has also been considered. This is already evident from the original paper by Holst. He sent some rock samples from Lake Mien to the petrographer Prof. F. Zirkel for microscopical studies. In a letter to Holst

lated March 13, 1888, Zirkel says [original German letter not located, translated into English from the Swedish translation in Holst's paper (p. 28)]: "Above all I must emphasize that practically all rock samples show an extraordinarily high degree of brecciation", and speaking about the rhyolites: "The rock samples do not in any way look like normal eruptive rocks, and I would not entirely reject the idea that a completely abnormal process is responsible for their genesis". In his short petrographic description of the rocks Zirkel repeatedly points out the peculiar character of the rocks. He also notes the rapid changes in the colour of the glass present in many of the rock samples.

In 1910, at a meeting of the Geological Society of Stockholm, A. G. Högbom<sup>4</sup> suggested, with every reservation, that the Lake Mien structure has an impact origin and compared it with Meteor Crater in Arizona. In 1963, Fredriksson and Wickman<sup>5</sup> pointed out that Lake Mien is among the five known geological structures in Sweden which are possible astroblemes.

The size of the Mien structure is not exactly known but must be of the order 4–5 km, or definitely smaller than the Ries Basin in Germany.

An interesting fact is that rocks from Lake Mien and uveites from the Ries Basin are so similar in appearance that they cannot be distinguished megascopically. We have therefore tried to detect coesite in the rocks of Lake Mien. Through the courtesy of Prof. W. von Engelhardt in Tübingen we have obtained coesite-bearing samples from Ries. By selecting similar-looking samples from Lake Mien we have succeeded in showing the presence of coesite in these rocks. The idea that Lake Mien is an impact structure is thus now strongly supported. A complete description of the work will be given by one of us (N. B. S.) in *Geol. Fören. Stockholm Förh.*

## CRYSTALLOGRAPHY

### Crystalloluminescence of Organic Compounds

THE crystallization of various inorganic compounds is known to be often accompanied by luminescence. Bright aminecence was observed visually in the crystallization of  $\text{Ba}(\text{BrO}_3)_2$  (ref. 1), in  $\text{As}_2\text{O}_3$  (ref. 2) from aqueous solutions containing HCl, in the crystallization of  $\text{K}_2\text{SO}_4$  (ref. 3) in the presence of  $\text{Na}_2\text{SO}_4$ , and in the precipitation of KCl or NaCl (ref. 4) from saturated aqueous solutions of HCl, or from ethanol. Photon counters have recorded luminescence in the visible and ultra-violet spectra of the crystallization of NaBr, KI,  $\text{BaCl}_2$ ,  $\text{NaNO}_3$  (refs. 5–8). Crystalloluminescence spectra coincide with those of photoluminescence. For example, crystallization of KI and KCl displayed luminescence in the regions of 80–480 and 240–380 m $\mu$ , respectively.

Though the detailed mechanism of luminescence excitation is not yet clear, energy considerations are no hindrance or explaining the phenomenon, as the crystal-lattice energy of ionic crystals is sufficiently high (100–170 kcal/mole), and corresponds to the luminescence region observed.

The heat of sublimation of molecular crystals is 4–15 cal/mole. The energy of one crystallization act obviously is insufficient for exciting luminescence in the visible

Fig. 1. Photoluminescence spectra: a, amide obtained by reaction of aniline with benzoyl chloride; b, amide purified by repeated crystallization and sublimation; c, benzoyl chloride; d, aniline

spectrum. Nevertheless, luminescence has been observed in the formation of molecular crystals<sup>9,10</sup>. It was recorded for the crystallization from organic solvents of uranine, eosine, 9,10-dibromoanthracene, of benzanilide and its derivatives, using a photometric device involving a photomultiplier as receiver of light. The spectral sensitivity of the photomultiplier was 350–610 m $\mu$ .

The crystalloluminescence of benzanilide used for kinetic studies of the reaction between aniline and benzoyl chloride<sup>9</sup> was investigated in more detail. The quantum yield of crystalloluminescence was estimated as one photon per  $10^{14}$  crystallization acts, by order of magnitude. The luminescence intensity was too low to use a spectral device. Consequently, a set of light filters was used. Spectral characteristics for the photoluminescence of solid benzanilide were obtained by means of the same light filters (Table 1). The spectra appeared to coincide. This may be seen from comparison of the transmittance ( $I/I_0$ ) of various light filters ( $I_0$  is the intensity in the absence of a light filter).

Light filter	Table 1				
	CC4	KC10	C3C-7	3C-7	C-3
Transmission band (m $\mu$ )	240–440	580–3000	380–550	380–450 500–580 550–620	380–450
Photoluminescence	0.50	0	0.88	0.37	0.30
Crystalloluminescence	0.52	0	0.87	0.37	0.30

The photoluminescence spectrum of solid benzanilide represents a broad band in the region of 380–550 m $\mu$  (Fig. 1). From Table 1, this spectrum may be considered as coinciding with that of crystalloluminescence. The same figure shows photoluminescence spectra of benzanilide, carefully purified by repeated crystallization and sublimation, benzoyl chloride and aniline. The photoluminescence spectra of benzoyl chloride and aniline were obtained at liquid nitrogen temperatures. It will be noted that the luminescence intensity of benzanilide shows a marked increase in the presence of KI, HCl, NaOH, while the spectrum remains independent of the nature of additives.

Photoluminescence was excited by the 3126 Å line of a mercury lamp. Absorption spectra of benzanilide, benzoyl chloride and aniline lie in the far ultra-violet. Consequently, it may be suggested that photoluminescence results from the crystalline nature of the systems. The additives will increase the luminescence quantum yield, as well as the absorption and emission capacities of crystals.

It may be seen from comparison of spectra (Fig. 1) that the four spectra exhibit identical luminescence bands seemingly due to the same excitation-levels.

Since the energy of a crystallization act is insufficient for excitation of luminescence, its mechanism for molecular crystals becomes even less clear. Luminescence is observed

both for crystallization and for dissolution of benzanilide, and this makes the phenomenon more complicated.

Analysis of the excitation mechanism is greatly hindered by the low value of the luminescence quantum yield ( $10^{-14}$ ), making it difficult to exclude mechanisms of low probability.

### Resin Vapour Replication Technique for Snow Crystals and Biological Specimens

Snow flakes have always been the object of interested observation because of their beauty, simplicity and diversity. A systematic study of them was first undertaken by Bentley, who painstakingly photographed thousands of them in the field<sup>1</sup>.

In 1941 Schaefer reported that he could make lasting replicas of snow crystals by coating them with a thin film of polyvinylformal in ethylene dichloride and allowing the plastic to harden while the solvent evaporated<sup>2</sup>. After the ice in the crystals had sublimed through the 'Formvar' film, large numbers of replicas remained which could be studied at will under the light microscope.

This method has recently been still further improved by Schaefer, by dropping the specimens on to dried 'Formvar' films and then exposing them to solvent vapours just long enough to soften the film and make the desired replicas<sup>3</sup>.

Both these processes, however, involve a liquid solution. Surface tension can cause the particles to become 'rafted'. It causes points and edges to become rounded, and uneven wall thicknesses can result. Nevertheless, these processes are admirably suited for replicating fully-grown snow flakes; but when replicating very small crystals, certain fine details internal and external are lost.

I have found that snow crystal replicas can be made with methyl 2-cyanoacrylate monomer (commercially available as Eastman's 910 Adhesive). The resin is applied through the vapour phase, eliminating the detrimental effects of a liquid medium. The monomer can polymerize on the surface of the crystal and can even penetrate into the interior via air channels (air inclusions).

Using a polarizing microscope, it was found that the replicas themselves are crystalline. Thus, it appears that the polymerization of the monomer does not take place at random sites but at precise locations governed by the molecular structure of the crystal surfaces. The replicas of the snow crystals obtained, therefore, are almost exact reproductions of the original crystals.

It can be observed that a crystal replica often has areas of intensely dark as well as very light regions. This is especially true when the crystal is examined in the electron microscope; the black areas represent areas of high electron absorption, which could result from a stereospecific polymerization. From other work (in preparation), it appears that the dark regions correspond to areas with a dominant positive charge, the light regions to areas of negative charge.

The methyl 2-cyanoacrylate molecule has two highly electronegative groups, a CN and a COOR radical<sup>4</sup>:

These two electron-rich centres of the monomer can co-ordinate directionally with the charged (ice) surfaces<sup>5</sup>. A positive surface would cause the CN and COOR groups to orient radially with the surface; the polymer would grow away from the ice in long chains. In the case of a negative surface, the monomer's electropositive carbons would tend to lie flat against the surface; polymerization could only take place horizontally with respect to the crystal surface, and a monomolecular film only one chain width thick would result. One can easily detect, therefore, the distribution of charge over the surfaces of the crystal.

If a bacterium is exposed to the resin vapour, the monomer penetrates wherever possible throughout the cell and again stereospecific polymerization is induced, with regional differentiation, as in the case of the snow crystals. As the resin can indicate the location and polarity of charged structures in the cell, it may also be of value in this application, as it has been in the case of the snow crystal.

Fig. 1. Typical hexagonal platelet with positively charged periphery and negatively charged interior ( $\times 3,520$ )

Fig. 2. Replicated ice needle, showing internal structure and charge distribution. Exterior surface is negatively charged ( $\times 8,640$ )

Fig. 3. Replicated frozen cloud droplet, showing considerable internal structure. External manifestations of the crystal structure are not yet evident at this early stage of development ( $\times 12,000$ )

The bacterial and crystal replicas may be best studied in the electron microscope. Here the light and dark areas can be readily identified. Replication of viruses for study with the electron microscope may also prove fruitful. Moreover, instead of replicating a cell such as a bacterium in bulk, it may be possible to prepare microsome sections of frozen cells and then replicate these thin sections with the resin; if this were done, it would be much easier to detect detail and charge distribution in the section examined.

Fig. 4. Replicated bacteria, showing locations of various charged surfaces within the cells

The procedure for replication is as follows: Apply one drop of methyl 2-cyanoacrylate to the surface of a glass slide and spread it into an even layer. Immediately hold it over the sample to be replicated. For small ice crystals, an exposure from 5 to 10 sec at a distance of 1 mm from the sample is sufficient. (The replication of large crystals has been less successful due to the thinness

of the replica walls.) For cells such as bacteria (in bulk) a 30-sec exposure is enough. Following the resin deposition, the ice in the snow crystals is allowed to sublime before coming to room temperature.

## CHEMISTRY

### Isotope Effect in the Benzene Synthesis for Radiocarbon Dating

As an alternative to the common gas sample methods for radiocarbon dating, liquid scintillation counting has been used and is being improved on. Relatively recently, a practically complete synthesis of benzene, one of the most efficient liquid scintillation materials, has been developed in Texas<sup>1,2</sup> and, independently, in the U.S.S.R.<sup>3</sup> The liquid, containing 92 per cent carbon, all of which comes from the sample being dated, can be produced in approximately 50 per cent yields in 8 h or less. The liquid scintillation counter, now in widespread use in biological and chemical tracer work, is well known for its exceptional reliability. Improvements in the photomultipliers and the introduction of fast electronics, which have substantially

Fig. 1. Distribution of 24 radiocarbon date pairs with the calculated errors based solely on the random nature of the disintegration process

Fig. 2. Distribution of the radiocarbon date pairs with additions of 40 and 80 years to the calculated errors to account for possible isotope effect variations

reduced the resolving time of the coincidence unit, have increased the counting efficiency for radiocarbon to 75 per cent or more. This is comparable to the gas sample counters. The stability of the liquid scintillation counter seems to be as good as that of the best gas counters.

At the present time, the principal objection to the liquid scintillation counting method for radiocarbon dating lies in the incomplete yields of the chemical syntheses. It could be expected that this would give rise to widely varying isotope effects, decreasing the precision of the dating. For example, an isotope effect of only 1 per cent would result in an error of 80 years in the date obtained. This is not important for samples older than a few thousand years, but could be significant for younger materials. Isotope effects of this magnitude have been noticed in acetylene counters<sup>4,5</sup> where the chemical yields vary from 80 to 100 per cent, but should not be present in those methods using carbon dioxide or methane. The

benzene technique, with its still lower chemical yields, could have large uncertainties due to isotope effects in the chemical syntheses. It is the purpose of this work to show that the objection is not valid and that the benzene liquid scintillator method for radiocarbon dating is as reliable, in all respects, as the gas counter procedures.

Some pertinent results from two laboratories using liquid scintillation counting are presented in Tables 1, 2 and 3. This group of data consists of archaeological and geological samples on each of which two completely independent datings were effected. In order to avoid a possible error arising from an inhomogeneity in the original sample, the material was first converted to carbon dioxide gas (in the Caracas laboratory) or strontium carbonate (in the Texas laboratory) and these pure compounds divided in half for the measurement pairs. This was not done for the check sample pairs shown in Table 3 or for Tx-127. The chemical synthesis methods of the University of Texas and the Instituto Venezolano de Investigaciones Científicas (I.V.I.C.) are similar, the main difference being in the acetylene production step. Texas uses the Suess method<sup>4</sup> modified as described previously<sup>1</sup>, and I.V.I.C. the Barker-Mackay technique<sup>6</sup>. The acetylene to benzene reaction catalyst is the same in the two laboratories.

I.V.I.C. uses a Packard Benzene Synthesizer Console while the University of Texas has hand-made systems for the chemical conversions. Both laboratories carry out the radioactivity measurements on Packard Tri-carb Liquid Scintillation Spectrometers and use the NBS Oxalic Acid C-14 Modern Standard.

In the three tables, the quoted errors in the ages or radiocarbon concentrations are based solely on the random nature of the radioactive decay and the background. No error is added for the uncertainty in the half-life of carbon-14. Comparisons of each measurement pair are expressed in multiples of the standard deviation and are given in the last columns of Tables 1-3.

The agreements of the 24 measurement pairs are presented graphically in Fig. 1 and compared with the expected Gaussian distribution. The fit is good. If non-reproducible isotope effects were significant and additional factors of 40 or 80 years (to account for effects of 0.5 and 1.0 per cent, respectively, in one of the samples of each pair) had to be added to the calculated errors, the results shown in Fig. 2 would be obtained. It is seen that these curves are far from the Gaussian distribution and that the agreement of the pairs is too good to be correct. The 80 years' addition gives a distribution clearly wrong. The 40 years' addition curve has an improbable distribution, but is not completely impossible.

There is a considerable amount of other evidence, that cannot be discussed here, supporting the absence of an important non-reproducible isotope effect. This involves the agreements found in multiple runs of the modern standards and, less rigorously, archaeological evidence on a large number of samples that strongly support the ages obtained. The accumulated data can be seen in the recent date-lists of the Texas and I.V.I.C. laboratories<sup>7-9</sup>.

In conclusion, it can be stated with some assurance that in the benzene liquid scintillator method, variations in the measured radioactivities due to causes other than the random nature of the disintegration process amount to

### Steric and Electronic Effects in Electron Transfer Reactions

THERE is at present no satisfactory theory to account for the rates of electron transfer from one metal ion to another via a bridging group. Two attempts have been made, both based on the assumption that the probability of electron transfer during the lifetime of the activated complex is small. The first relationship took the form<sup>1</sup>:

$$k_{bi} \cong k_f(C_1 P_{rs} \tau)^2$$

where  $k_{bi}$  is the observed overall rate constant for the reaction,  $k_f$  is the rate constant for the formation of the activated complex,  $C_1$  is a constant, and  $P_{rs}$  the mobile bond order<sup>2</sup> between the atoms  $r$  and  $s$  associated with the metal ions.  $\tau$  is the mean lifetime of the activated complex. This conjugation theory of electron transfer was extended by including the effect of charged reactants on the rate of formation and the mean lifetime of the activated complex<sup>3</sup>, giving at zero ionic strength the relationship:

$$\ln K_0 = C_0 + \ln p_{rs}^2 - \frac{3Z_A Z_B e^2}{DkT r_{AB}}$$

where  $Z_A$  and  $Z_B$  are the charges on the ions  $A$  and  $B$ ,  $C_0$  is a constant,  $D$  is the dielectric constant of the medium,  $k$  is the Boltzmann constant,  $T$  is the temperature, and  $r_{AB}$  the distance between the metal centres. A comparison has been made<sup>4</sup> with results obtained experimentally in the chromium(II) reduction of various pentamminecobalt(III) complexes. Agreement is better with the second theory than with the first, but not good. The suggestion was made that improvement of the M.O. calculations and the electrostatic treatment might produce substantial numerical agreement. Neither theory takes into account the steric effects of substituent groups (that is, groups present as part of the ligand but not participating directly in the electron transfer path). Such groups are important: the rate constants for the reduction of  $(\text{NH}_3)_5\text{CoO}_2\text{C-R}^{2+}$  fall off from  $0.32 \text{ M}^{-1} \text{ sec}^{-1}$  to  $0.04 \text{ M}^{-1} \text{ sec}^{-1}$  as  $R$  changes from  $\text{CH}_3$  to  $\text{cycloC}_6\text{H}_{11}$ , even though the path length for the electron transfer remains unchanged<sup>5</sup>.

Fig. 1 shows a plot of some rate constants as a function of Taft's  $\sigma^*$  parameter<sup>6</sup>. In all cases, the electron transfer path is  $\text{metal}_A\text{—O—C—O—metal}_B$ . Since the van der Waals radius of a  $\text{—CH}_3$  group is almost identical<sup>6</sup> with that of a  $\text{—Br}$ , the steric effects in the two ligands should be the same, so that  $\rho^*$  in the Taft equation:

$$\log k - \log k_{\text{ref.}} = \rho^* \sigma^* + E_s$$

( $E_s$  is the steric factor) can be evaluated for the electron transfer process. The experimental value is  $-0.04$ ,

Fig. 1. Rate constants,  $k$ , for the chromium(II) reduction of carboxylatopentamminecobalt(III) complexes  $(\text{NH}_3)_5\text{CoO}_2\text{C—R}^{2+}$  plotted against  $\sigma^*$  values of  $R$ .

similar to the values obtained for the acid hydrolysis of carboxylic esters. If a line with this slope is drawn through the value for the reference compound (acetatopentamminecobalt(III),  $R = \text{—CH}_3$ ), the  $E_s$  values for the other substituents can be obtained. The values are shown in Table 1. With the exception of that for the dichloromethylene, the  $E_s$  values follow the same trend previously found in ester hydrolyses<sup>7</sup>, indicating that any electron transfer theory proposed for bridging reactions must take into account not only the mobile bond order of the bridge and the distance between the metal centres, but also the steric effects of the ligands.

If the bond order is calculated without consideration of the electronic substituent effects, the empirical relationship at  $25^\circ$  and ionic strength equal to 1 is:

$$\log k_{bi} = 7.28 + \log p_{rs}^2 + \rho^* \sigma^* - \frac{3Z_A Z_B e^2}{DkT r_{AB}} + E_s$$

Similar considerations seem to apply in the electron transfer through *ortho* substituted benzoates, where the experimental data are much more limited.

The importance of the  $\sigma^*$  parameter was suggested by Dr. R. G. Linck, Wright-Patterson Air Force Base, Ohio. This research was supported by grants from the National Science Foundation and the Alfred P. Sloan Foundation.

### Activated Chemisorption of Hydrogen on Copper Films

THE well-known dissociative adsorption of hydrogen on transition metal films has been reported<sup>1</sup> not to occur on evaporated copper films. Copper is catalytically active in hydrogenation reactions, and copper powders prepared by reduction of the oxide have been shown<sup>2</sup> to adsorb hydrogen. It is not certain that the surfaces were clean and it has been suggested<sup>3</sup> that the observed adsorption may be due to impurities. Kwan<sup>4</sup> found a slight activated chemisorption at high temperatures on very carefully reduced copper powder.

On the other hand, surface potential studies<sup>5</sup> of atomic hydrogen adsorption, together with the kinetics of the ortho-para hydrogen conversion reaction<sup>6</sup>, suggested that activated dissociative adsorption should be observable on evaporated films under suitable conditions. The failure to observe adsorption was attributed to an activation energy barrier at  $-78^{\circ}\text{C}$  or lower and to the relatively high equilibrium pressure required for moderate coverage at  $0^{\circ}\text{C}$ . The latter factor and the small surface area of copper films at  $0^{\circ}\text{C}$  render conventional gas volumetric methods insensitive, but some evidence for adsorption at  $0^{\circ}\text{C}$  has been reported<sup>7</sup>.

The presence of chemisorbed hydrogen should be revealed by its surface potential, which can be measured at high equilibrium pressures by the vibrating condenser method. A diode cell similar to that previously used<sup>7</sup> has been adapted by the addition of an extra stem to the film bulb. This stem carries a vibrating reference electrode assembly which may be lifted magnetically *in vacuo* leaving the bulb clear for film deposition and diode measurements. When the latter have been carried out the vibrating electrode can be lowered into position parallel to a flattened section of the bulb wall.

Fig. 1. Surface potential of hydrogen on copper film as function of temperature at 11 mm Hg pressure

The diagram (Fig. 1) shows how the surface potential varies with temperature at a constant pressure of 11 mm Hg on a copper film deposited at  $20^{\circ}\text{C}$ . Complete desorption occurred on pumping. Diode measurements with atomic hydrogen before and after the vibrating condenser measurements gave a rather high maximum surface potential at  $-78^{\circ}\text{C}$  of  $-0.28\text{ V}$ . It seems reasonable to suppose that the surface potential measured by the vibrating condenser was due to chemisorbed hydrogen and hence that the coverage was appreciable. A second film deposited at  $20^{\circ}\text{C}$  gave a more typical surface potential of  $-0.24\text{ V}$  at  $-78^{\circ}\text{C}$  with atomic hydrogen. At  $-4^{\circ}\text{C}$ , vibrating condenser measurements showed the adsorption of hydrogen, equilibrating within a few minutes and with a surface potential rising to about  $-0.23\text{ V}$  as the pressure was increased to 30 mm. The change of

surface potential with pressure was then very small. These results indicate that clean copper does dissociatively chemisorb hydrogen under suitable conditions. Further studies of the equilibria and kinetics of the process are planned.

### Hydration of Calcium Sulphate Hemihydrate

IN *Nature* of October 3, 1964, M. J. Ridge discusses the hydration of calcium sulphate hemihydrate on which he modifies his previous views. The mechanism proposed is somewhat similar to that put forward by me at the fourth international symposium on the "Reactivity of Solids"<sup>1</sup> and published in greater detail in subsequent communications<sup>2-4</sup>. However, Mr. Ridge's theory remains open to several objections.

(1) As was pointed out in ref. 2 the fact that the newly-formed gypsum crystals appear in the shape of plates and needles does not imply that their surface area will increase proportionately with the mass. This is not even true approximately. A plate will appear if the growth in one of three mutually perpendicular directions is considerably smaller than the other two and the needle if the growth in two is considerably smaller than the one in the remaining third. For constant, though different, speeds in all three directions the volume (and therefore the mass) will increase proportionately with  $t^3$  and the surface area with  $t^2$ .

(2) It is true that the rates of growth and dissolution may be assumed to be proportional to the surface area; however, these rates are also dependent on the under-saturation and super-saturation of the solution in the neighbourhood of the old and new phases. This depends on the concentration of  $\text{CaSO}_4$  in the suspending liquid, being at first equal to the pseudo solubility of the hemihydrate and being finally equal to the solubility of gypsum which is considerably smaller; this was shown repeatedly experimentally, for example by Birss and Thorvaldson<sup>5</sup>. Such a pronounced change of concentration cannot be expected to be without effect on the hydration. It can also be derived theoretically, as will be shown in a forthcoming paper.

(3) Mr. Ridge's modified differential equation is close to the simplified equation (15) in ref. 2. It differs only by replacing the power index  $2/3$  of  $\alpha$  by 1. This will evidently be of little consequence at the later stages of hydration when  $\alpha$  itself approaches 1 but may lead to significant differences at the beginning of the hydration period. At the beginning of the hydration Mr. Ridge's theory gives  $d\alpha/dt \sim \alpha$  as in his unmodified theory, from which it follows that  $\alpha \equiv 0$ , that is, no hydration at all unless there is some gypsum present at the very beginning ( $P \neq 0$ ). This is also the trivial solution of the modified differential equation now proposed. On the other hand, if at the beginning  $d\alpha/dt \sim \alpha^{2/3}$  as previously demonstrated<sup>2</sup>  $\alpha \sim t^3$  even if there is no trace of gypsum initially. The mass of the crystal increases proportionally to the cube of the time; this would be expected initially from a crystal growing in every direction.

(4) The one example shown fits the equation derived very well, but it should be noted that  $\alpha$  occurs in the

quation always under a cube root, and under either the  $n$  or the  $\tan^{-1}$  so that the expression is very insensitive to any error in  $\alpha$ . It is perhaps significant that the point corresponding to the start of the hydration ( $\alpha = 0.012$ ) is the worst fitting one.

Schiller, K., *J. App. Chem.*, **13**, 572 (1963).

Schiller, K., *J. App. Chem.*, **14**, 209 (1964).

Birss, F. W., and Thorvaldson, T., *Canad. J. Chem.*, **33**, 870 (1955).

I FEEL that Schiller may be under some misapprehension regarding our previous work. The differential equation, the solution of which forms my complete equation for the hydration of calcium sulphate hemihydrate, was derived from one developed earlier to account for the self-acceleration of the reaction<sup>1-6</sup> by the inclusion of a term allowing for processes leading to the decay of the rate. Contrary to Schiller's statement (preceding communication), I have not modified my views, but have expressed them more completely in mathematical terms. The differential equation resembles one quoted by Schiller<sup>7</sup> but not derived precisely from a model. The equation mentioned by Schiller is well known for dealing with the formation and growth of nuclei of a solid product (for example, see ref. 8), and he has not tested to what extent a solution describes experimental observations in the particular system. The differences between the two equations are highly significant.

My replies to Schiller's four objections are as follows:

(1) If needles grow exclusively along the long axis and plates in two dimensions parallel to their planes the surface area is approximately proportional to mass, the approximation being better the smaller the unchanging dimensions. This is the condition for the growth of gypsum in my theoretical model, and its aptness for the accelerated and unmodified reaction is borne out by the experimental results. Schiller considers only growth in three dimensions, when a two-thirds relationship will apply as discussed earlier<sup>8</sup>. However, my model is theoretically possible, and in my opinion provides a better basis for interpreting the rate of the accelerated and unmodified reactions than does one assuming growth in three dimensions. The model leading to a two-thirds relationship between the mass and surface area of the system of growing gypsum crystals may be better for interpreting the more complex reaction occurring in the presence of inhibitors which tend to result in equi-axial crystals of gypsum, as we have suggested already<sup>9</sup>.

(2) I am aware of the questions of under-saturation and super-saturation raised by Schiller<sup>4</sup>, but they do not appear to complicate the matter seriously as shown by the accord between experimental results and a theory which ignores them. The probable reason for this is that a steady state regarding concentration gradients will be set up in the kinetically important parts of the system before much hemihydrate has been hydrated. This situation can result from the low solubility of calcium sulphate and the fact that by far the greater part of it in the system is solid.

(3) The difference in power index between my differential equation and that quoted by Schiller makes a considerable difference so far as the first half of the reaction is concerned, and particularly regarding nucleation, as Schiller admits in his third objection. The implication that "there will be no hydration unless some gypsum is present" is in accord with the heterogeneous nature of nucleation in the system. As explained elsewhere<sup>6</sup>, the population of seeding nuclei results in gypsum being present in effect at the

beginning of the reaction, although the hemihydrate need contain no gypsum as such.

(4) The mathematical argument that the expression  $F(\alpha)$  is insensitive to error is incorrect.  $F(\alpha)$  is a function of a single variable, and will respond (unless it is constant) equally to any variation in  $\alpha$  whether this is due to error in measurement or to a real change in the system.

Schiller obtains the differential equation<sup>7,10</sup> to which he refers by a considerable approximation from another equation derived from a mechanism that he develops in the series of papers quoted. In them, Schiller treats an equation (No. 11, ref. 9) as the true outcome of his method. I have tested his equation No. 11 with results obtained from the isothermal hydration of calcium sulphate hemihydrate and find that it does not represent them very well. Schiller uses the increase in temperature of the system to test his equation. It is true that we have shown theoretically and experimentally<sup>2-6</sup> that the courses of the adiabatic and isothermal reactions are not very different for the accelerated and unmodified reactions (but not for the inhibited reaction<sup>6</sup>); but it is nevertheless desirable that equations that are derived for isothermal conditions or on the assumption that the temperature coefficient is small should be tested with data from isothermal hydration, and this Schiller has not done.

### Thermal Decomposition of Irradiated Strontium Azide

MAGGS<sup>1</sup> showed that the isothermal decomposition of strontium azide is characterized by a marked induction period during which no appreciable volume of gas is liberated. This is followed by a period of acceleration during which an exponential relationship:

$$\log p = k_1 t + c_1 \quad (1)$$

is obeyed.

Garner and Reeves<sup>2</sup> obtained a better fit of the  $p/t$  plots using the power law:

$$p^{1/n} = k_2 t \quad (2)$$

where  $n = 3$ . They also studied the effect of pre-irradiation of the azide by ultra-violet light and found: (i) that agreement with the power law (with  $n = 3$ ) improved, (ii) the induction period was shortened, and (iii) the values of  $k_2$  increased, as the times of pre-irradiation increased. Maggs<sup>1</sup> also studied the effect of the emission from radium on the rate of decomposition. The radium was kept in a glass phial adjacent to the surface of the azide during evacuation of the apparatus and also during the decomposition. At 109.5°C the induction period was halved, and  $k_1$  increased three-fold after an initial evacuation for 15-16 h.

Sviridov<sup>3</sup> found that strontium azide pre-irradiated in air at room temperature for 1 min by X-rays (25 kV and 14 m.amp) decomposed at 126°C at a greatly increased rate. In 20 min, 30 per cent decomposition occurred.

whereas with the unirradiated salt the first sign of decomposition occurred only after 3 h.

Difficulties are experienced in obtaining uniform pre-irradiation with ultra-violet light and X-rays and obviously a systematic study of the effect of the emission by radium is difficult under the conditions used by Maggs. However, pre-irradiation with  $\gamma$ -rays is capable of more precise control and has the advantage that it may be done under vacuum without any possible reaction between air and any nuclei which may be formed, and also that irradiation effects will occur throughout the solid. Marked effects on the subsequent thermal decomposition of barium azide<sup>4</sup> and permanganates<sup>5</sup> have been found after pre-irradiation with 1-MeV  $\gamma$ -rays.

Strontium azide was prepared by the method of Garner and Reeves and recrystallized three times from water. A typical  $p/t$  plot is shown in Fig. 1 with the mathematical analysis. The power law, with  $n = 3$ , fits the acceleratory period in the temperature range 124°–147° C. The decay reaction conforms to the unimolecular decay law equation:

$$\log(p_f - p) = k_3 t + c_3 \quad (3)$$

where  $p_f$  is the final pressure.

The effect of pre-irradiation by  $\sim 1$ -MeV  $\gamma$ -rays is extremely marked. Previous studies of the effects of pre-irradiation by  $\gamma$ -rays on the thermal decomposition of permanganates<sup>5</sup>, ammonium dichromate<sup>6</sup>, nickel<sup>7</sup>, mercuric<sup>8</sup> and lead oxalates<sup>9</sup>, and barium azide<sup>4</sup>, have been made and we find that the sensitivity of strontium azide to  $\gamma$ -rays far exceeds that of any of these substances.

After irradiation (20 Mrads) at room temperature, *in vacuo*, the salt is a light-grey colour. After a dose of 1 Mrad it is still white. Fig. 2 shows the effect of pre-

Fig. 1. Curve A, plot of pressure against time for decomposition of 5 mg strontium azide at 132° C; line B,  $p^{1/3}$  against  $t$ ; line C,  $\log(p_f - p)$  against  $t$

Fig. 2. Effect of pre-irradiation by  $\gamma$ -rays (dose 10 Mrads) on thermal decomposition of strontium azide at 124° C. Curve A, unirradiated; curve B, irradiated

Fig. 3. Effect of varying  $\gamma$ -ray dose on the thermal decomposition of strontium azide at 96° C. Doses: A, 0 rad; B, 1,000 rads; C, 10,000 rads; D, 100,000 rads; E, 1 Mrad; F, 20 Mrads. The induction period for A ended at 700 min

Fig. 4. Curve A, plot of pressure against time for decomposition of  $\gamma$ -irradiated (5 Mrads) at 96° C; line B,  $\log p$  against  $t$ ; line C,  $\log(p_f - p)$  against  $t$

irradiation on the subsequent thermal decomposition. The irradiation effect is produced without measurable loss of gaseous product because the final pressure, for a fixed weight of salt, is independent of the dose. Fig. 3 shows the effect of varying the  $\gamma$ -ray dose.

The power law no longer fits the acceleratory region of the  $p/t$  plots for pre-irradiated azide. Conformity to the power law with  $n = 3$  with unirradiated crystals indicates reaction at a fixed number of nuclei and the growth of these reaction centres in a three-dimensional manner. With irradiated crystals it is expected that the number of nuclei would be increased by irradiation, and as the reaction progresses this number would possibly increase as incipient nuclei become actual growth centres. Such a phenomenon would give higher values to  $n$  in equation (2). However, the power law does not fit the acceleratory period, nor does the Avrami-Erofeyev equation<sup>10</sup>. The Prout-Tompkins<sup>11</sup> equation and the modified form<sup>12</sup> of this equation do not define the plots either.

However, successful analyses are obtained using the exponential law, equation (1), for samples pre-irradiated to a dose of 1 Mrad and higher. Below this dose neither the power law nor exponential law holds throughout the acceleratory period although the extent of fit of the power law improves with decreasing dose, and with the 1,000-rads specimen the fit is from  $\alpha = 0.03$  to  $\alpha = 0.5$ . The decay reaction is described by the unimolecular decay law, equation (3). Fig. 4 shows a typical mathematical analysis.

The exponential law has been used by Garner and Hailes<sup>13</sup> in the study of the decomposition of whole crystals of mercury fulminate. It can be derived theoretically

ing the concept of nuclei as linear, branching chains, or anchoring plate-like nuclei. The formation of additional nuclei by the chain mechanism is a much more important process than the formation of fresh nuclei. The chains could be reaction ones along dislocation lines from nuclei situated there, or they could be branching plate-like nuclei at sub-grain boundaries. The latter possibility is preferable since it would account for a large percentage decomposition before the decay reaction commences; in our studies this occurs at  $\alpha = 0.50$ . The applicability of the bimolecular decay law indicates that in the remaining isolated blocks each molecule possesses an equal probability for decomposition, and thus the rate of reaction is simply proportional to the amount of substance undecomposed.

This study is being continued and electrical conductivity measurements of irradiated and unirradiated crystals are being made. The results will be presented in full elsewhere.

We thank the South African Council for Scientific and Industrial Research for financial assistance, and Messrs. African Explosives and Chemical Industries for a research fellowship held by one of us (D. J. M.).

## BIOCHEMISTRY

### RNA Synthesis in Normal Leucocytes, Leukaemia and Macroglobulinaemia

DIFFERENCES in the sedimentation characteristics and incorporation of radioactive precursors in the RNA of *leu*La cells, ascites tumour cells and rat liver tissue have been reported<sup>1-3</sup>. Marks *et al.*<sup>4</sup>, in the course of extensive studies on RNA synthesis in reticulocytes, reported that apidly-labelled RNA was absent from reticulocytes while it could be detected in leucocytes from normal subjects and patients with chronic lymphocytic leukaemia<sup>5</sup>. The present report describes patterns of RNA synthesis in the leucocytes from patients with leukaemia or macroglobulinaemia and from normal subjects.

Uridine-2-<sup>14</sup>C (specific activity 20–50  $\mu\text{C}/\mu\text{mole}$ ) was obtained from the New England Nuclear Corporation. Bentonite was purchased from the Fisher Scientific Co. and prepared according to Fraenkel-Conrat *et al.*<sup>6</sup>. Venous blood was treated with heparin (0.1 mg/ml.) and incubated at 37° C with 0.1  $\mu\text{C}/\text{ml.}$  of uridine-2-<sup>14</sup>C. The last hour of incubation was carried out in graduated cylinders inclined at 45° to accelerate sedimentation. At the end of 30, 90, 180 and 360 min, aliquots were removed and cooled at 4° C. Leucocytes were isolated as previously described<sup>7</sup>. RNA was extracted by the method of Eason, Cline and Mellie<sup>8</sup>, modified in the following ways: (1) All procedures were carried out at 4° C. (2) Treatment with DNase was omitted. (3) Dialysis of the RNA was usually omitted. RNA was subjected to sucrose gradient centrifugation for 13 h at 23,000 r.p.m. in a Spinco Model L ultracentrifuge using the SW 39 swinging bucket. Optical density at

Fig. 1. Sucrose density gradient analysis of RNA from leucocytes of a patient with macroglobulinaemia. The leucocytes had been incubated with <sup>14</sup>C-uridine for 30 min (upper left), 90 min (upper right) and 180 min (lower left). The lower right curve shows the 180-min incubation pattern in RNA obtained following treatment of the patient. ▲—▲, optical density; ●—●, radioactivity.

260 m $\mu$  was determined in a Gilford spectrophotometer, and the radioactivity incorporated was quantitated with either a thin-window gas flow counter or a liquid scintillation counter. RNA was studied from the leucocytes of 7 patients with chronic lymphocytic leukaemia, 5 patients with chronic myelocytic leukaemia and 3 patients with acute leukaemia. All but 3 of the patients were studied on at least two occasions. Agreement of the specific activities of the newly formed RNA in a given untreated patient when studied on different days was within 20 per cent, reflecting the general reproducibility of the incubation, extraction and sedimentation procedure. All the patients were in haematological relapse and were either untreated or had just been started on therapy when studied. One patient with macroglobulinaemia was studied on three occasions. At the time of the first study, the leucocyte count was 60,000 cells/mm<sup>3</sup> and consisted mainly of plasma cell-like lymphocytes. Four laboratory workers served as the donors of normal leucocytes.

The sedimentation profile in sucrose gradient centrifugation of RNA extracted from leucocytes of a patient with macroglobulinaemia (J. R.) is shown in Fig. 1. In the aliquots, removed after 30, 90 and 180 min of incubation, three peaks of optical density at 260 m $\mu$  were identified corresponding to 28S, 16S and 4S material. The incorporated radioactivity, indicated with the dotted line in Fig. 1, shows that the label first appeared in the 4S material in the 30-min sample. After 90 min a small amount of radioactivity is found in the heavier RNA, and uniform labelling is seen after 3 h incubation. The counts precipitated by trichloroacetic acid became non-acid-precipitable after treatment with ribonuclease. Following therapy with chlorambucil, the patient's white blood count decreased to 13,000 cells/mm<sup>3</sup> and plasma cell-like lymphocytes disappeared from the circulation. The patient's differential count and the optical density sedimentation profile obtained at that time resembled that of normal leucocytes. There has been over a 50-fold decrease in specific activity when compared to the previous study, and there is no label incorporated in the 16S and 28S material after 3 h.

In all normal subjects studied, the optical density profile showed the same 28S, 16S and 4S peaks found in the macroglobulinaemic or leukaemic subjects. However, characteristically the specific activity of the 28S and 16S RNA was an order of magnitude lower than seen in the macroglobulinaemic cells when the patient was studied before therapy. The incorporation in J. R. after therapy is lower than that found in any normal subject.

Representative patterns after 3 h of incubation with radioactive uridine are shown in Fig. 2 for cells of chronic myelocytic leukaemia, chronic lymphocytic leukaemia, acute myeloblastic leukaemia and acute monocytic leukaemia. In contrast to the pattern found in macroglobulinaemia, incorporation of radioactivity into the RNA of the leucocytes in chronic myelocytic leukaemia and acute myeloblastic leukaemia is very low, the ratio of radioactivity to optical density being significantly less than in the macroglobulinaemic cells in the 4S material, with essentially no incorporation into the 28S and 16S RNA following an incubation period of 3 h. After 6 h incubation under the above conditions slight incorporation of label was noted in the 16S and 28S RNA, comparable in specific activity to normal leukocytes. Among the 7 patients with chronic lymphocytic leukaemia who were investigated, a consistent reproducible difference was noted in that the specific activity of the RNA in 5 of the patients ranged from 2 to 5 times that of normal leukocytes, while the other 2 patients had normal patterns. In cells of the high synthesis group label appeared in the 28S and 16S RNA between 1 and 3 h, rather than after 6 h, incubation. The profile shown in Fig. 2 (lower left) represents a patient from the group with high RNA synthesis rates, while patients in the low synthesis group would have patterns resembling that shown in the upper right of the figure. The patient with acute monocytic leukaemia shown in the lower right had active RNA synthesis.

Fig. 2. Sucrose density gradient analysis of leucocyte RNA from patients with leukaemia. Leucocytes were incubated for 18/80 min with  $^{14}\text{C}$ -uridine. Upper left: chronic myelocytic leukaemia. Upper right: acute myeloblastic leukaemia. Lower left: chronic lymphocytic leukaemia. Lower right: acute monocytic leukaemia.  $\Delta$ — $\Delta$ , optical density;  $\bullet$ — $\bullet$ , radioactivity

Experiments where  $^{32}\text{P}$  or  $^3\text{H}$  uridine were used to label RNA confirmed the above results. In two experiments the extracted 4S material was concentrated and hydrolysed with 0.3 M KOH, and the 2'3-nucleotides were separated by electrophoresis<sup>9</sup>. When  $^{14}\text{C}$  uridine was used as a label, equal incorporation into U and C was noted, indicating that RNA synthesis rather than turnover of the A-C-C terminal was taking place.

The present studies reveal heterogeneity in the patterns of RNA synthesis in human leukocytes. The high rate of synthesis in macroglobulinaemic cells is not unexpected in view of the marked synthesis of protein *in vivo* and *in vitro* observed in this disorder. The evaluation of inhibitors of RNA synthesis may be relevant to therapy. Evidence of heterogeneity is found among patients with chronic lymphocytic leukaemia who have identical cell morphology. It remains to be determined whether these changes can be correlated with protein turnover, mitotic activity or infection of the cell by viral agents.

### Determination of Purines in the Presence of Proteins: Steady-state Levels of Xanthine Plus Hypoxanthine in Rat Liver

DURING an investigation of the influence of tissue xanthine oxidase concentration on the corresponding steady-state levels of hypoxanthine plus xanthine in rat liver (cf. Haddow *et al.*<sup>1</sup>), the recovery of added xanthine, hypoxanthine and uric acid was found to be low.

This problem is not new, since the assay of serum uric acid is complicated in a similar manner<sup>2</sup>. Xanthine and purine are known to bind to certain proteins<sup>3,4</sup>. Xanthine in solution when added to the precipitated tissue proteins was only incompletely removed by repeated washing with 8 per cent perchloric acid solution (recovery was 30–50 per cent depending on the ratio of xanthine to liver). It would thus appear that the losses are due to adsorption of the purines on the precipitated proteins. Complete recovery ( $98 \pm 3$  per cent) may be achieved, however, if the protein precipitant used is lithium perchlorate. The effect is not observed if the lithium hydroxide used is replaced by an equivalent amount of sodium hydroxide.

The following procedure has been found suitable in the case of hypoxanthine plus xanthine and uric acid in liver. A modified method may prove suitable for determining the ratio of free to bound purine in tissues and may possibly be extended to similar investigations in other compounds which are non-specifically bound to proteins. The animals were killed by ether anaesthesia according to Dale<sup>5</sup>. The livers were excised and placed immediately into liquid nitrogen. Weighed amounts of frozen liver were homogenized in twice the volume of 0.45 M lithium perchlorate and the protein plug washed twice with small volumes of the lithium perchlorate solution. The supernatant and washings were combined and neutralized with potassium hydroxide<sup>7</sup>. Xanthine plus hypoxanthine was measured spectrophotometrically by conversion to uric acid utilizing xanthine oxidase<sup>8</sup>. The lowest level which could be measured under these conditions was 0.03  $\mu\text{moles/g}$  wet weight of tissue.

Using the foregoing method an attempt was made to determine the normal steady-state level of xanthine plus hypoxanthine in the liver of the female rat (C.B., Hooded and August strains), female mouse (C<sup>+</sup>) and hen (White

Table 1. DEVELOPMENT OF HYPOXANTHINE PLUS XANTHINE ( $\mu\text{g/g}$  WET WEIGHT OF TISSUE) IN RAT LIVER ON STORAGE AT VARIOUS TEMPERATURES

Time after death	0 min*	5 min	1 h	4 h
24° C	0	30	65	150
4° C	0	8	40	80
-13° C	0	0	0	8

\* Time was measured from point at which liver was removed from animal.

eghorn). A value of less than 0.03  $\mu$ moles/g wet weight was obtained. However, if the method of killing the animal was changed to cervical dislocation, then a value comparable with that obtained by Reid and Stevens<sup>5</sup> was found (0.08  $\mu$ moles/g wet weight of liver in C.B. strain rats). Dale<sup>6</sup> has commented on the effect of stress on the levels of labile metabolites and has suggested that ether anaesthesia is preferable to cervical dislocation in this respect.

Livers were also removed from animals and stored at three different temperatures ( $-13^{\circ}\text{C}$ ,  $+4^{\circ}\text{C}$  and  $+24^{\circ}\text{C}$ ) to see if any alteration in the level of the metabolites had occurred. As expected it was found that enzyme reactions must be quenched by extremely rapid cooling immediately in the animals' death (see Table 1). Even when the rat liver was stored at  $-13^{\circ}\text{C}$ , a gradual rise was observed after the first hour.

If one accepts that the low level of xanthine and hypoxanthine observed represents the true *in vivo* steady-state level, then xanthine oxidase is not a rate-limiting enzyme of purine catabolism under these conditions.

I thank Prof. F. Bergel and Dr. R. C. Bray for their interest, and Dr. D. A. Gilbert for helpful discussions. This work was carried out while I was the recipient of a Royal Marsden Hospital studentship. ### Structure of a Dopa Glucoside from *Vicia faba*

$\beta$ -(3,4-Dihydroxyphenyl)-L-alanine (L-DOPA) has only been detected in a limited number of plants, and it appears to be confined mainly to leguminous species. Unlike most other phenols of low molecular weight, however, it exists in relatively high concentrations in the free state. This is particularly the case, for example, with the broad-bean, *Vicia faba*<sup>1</sup>, but Nagasawa and his associates<sup>2</sup> have also isolated an O- $\beta$ -D-glucoside of DOPA from the testa of the bean seed. The Japanese workers did not, however, determine whether it was a 3- or 4-O substituted derivative and in view of our interest in the formation and metabolism of DOPA in plants we have reinvestigated the structure and distribution of this compound.

As *V. faba* contains only small amounts of this DOPA glucoside a preliminary examination of the glucoside obtained in high yield by feeding *Pisum sativum* seeds with DOPA was undertaken and a comparison then made of this compound with the corresponding derivative obtained from the bean.

Seeds of *P. sativum* var. 'Early Onward' were soaked overnight in a saturated solution of L-DOPA. They were then washed and left on moist cotton wool for 4 days in the dark (cf. Pridham and Saltmarsh<sup>3</sup>). The resulting seedlings were extracted with aqueous ethanol (80 per

cent) and the concentrated extract was examined on paper chromatograms. This showed the presence of at least five compounds which are not normally present in the tissues. By careful fractionation of the extract on paper, using ethyl acetate/acetic acid/water (9:2:2 v/v) solvent followed by electrophoresis (0.1-M formic acid, pH 2.4, 4,000 V/1 h), a small quantity of a compound,  $P_2$ , was isolated as a syrup which was freeze-dried to a hygroscopic powder. Hydrolysis of  $P_2$  with  $\text{N H}_2\text{SO}_4$ ,  $\text{N HCl}$ , 50 per cent formic acid or  $\beta$ -D-glucoside glucosylhydrolase yielded only DOPA and D-glucose in the molar ratio of 1:1. The configuration of the glucose was determined by reaction with D-glucose oxido-reductase, and the rate of acid hydrolysis of  $P_2$  suggested that the glucosyl residue was in the pyranoid form.

$\beta$ -(3-Hydroxy-4-methoxyphenyl)-DL-alanine and  $\beta$ -(3-methoxy-4-hydroxyphenyl)-DL-alanine were synthesized as model compounds and their colour reactions with diazotized *p*-nitroaniline/NaOH and ultra-violet spectra under neutral and alkaline conditions determined. This revealed several significant differences between the 3-O- and 4-O-substituted compounds and in particular a variation in the relative absorbance at  $\sim 240$  and  $\sim 295 \text{ m}\mu$  on addition of alkali.  $P_2$  had all the characteristics of a 3-O-substituted DOPA. The absence of a free O-dihydroxyl grouping was further indicated by the fact that it gave no colour reaction with aqueous sodium molybdate and did not exhibit a characteristic hypsochromic shift in spectrum under alkaline conditions when treated with borate.

Confirmation of the position of the D-glucopyranosyl residue on the aromatic ring was obtained after methylation of  $P_2$  by the Kuhn procedure with methyl iodide and silver oxide in dimethylformamide<sup>4</sup>. Alkaline nitrobenzene oxidation<sup>5</sup> of the methylated derivative gave rise to isovanillin as the only aldehydic product. This was characterized by paper electrophoresis using phosphate buffers at pH 8.7 and 10.0, with 2,4-dinitrophenylhydrazine/NaOH as the locating reagent (isovanillin is readily distinguished from vanillin by this method as the latter possesses a more strongly dissociated phenolic hydroxyl group).

The cotyledons from 4-day-old broad-bean (var. 'Johnson's Longpod') seedlings were extracted and examined by the same procedure, and a compound identical to  $P_2$  in all respects was isolated. The conclusion is, therefore, that both  $P_2$  and the derivative from *V. faba* are  $\beta$ -[3-( $\beta$ -D-glucopyranosyloxy)-4-hydroxyphenyl]-L-alanine. The colour reactions and chromatographic and electrophoretic behaviour of this compound are summarized in Table 1.

Table 1. PROPERTIES OF DOPA GLUCOSIDE

Colour reaction with: Diazotized <i>p</i> -nitroaniline/NaOH Ninhydrin Sodium molybdate	$P_2$ and <i>V. faba</i> glucoside

Ethyl acetate/acetic acid/formic acid/water (18:3:1:4, v/v)	0.37
Ethyl acetate/pyridine/water (10:4:3, v/v)	0.56
Butan-1-ol saturated with water	0.30
<i>M<sub>DOPA</sub></i> values*	
0.1 M formic acid (pH 2.4)	0.85

\* Electrophoretic mobility relative to L-DOPA, corrected for electroendosmosis.

Nagasawa and his colleagues<sup>2</sup> reported that DOPA glucoside occurred mainly in the green testa of a late ripening variety of *V. faba* and to a lesser extent in the hilum and the inner tissue of the pod. Our own chromatographic investigations with the 'Johnson's Longpod' variety confirm their findings but also suggest that this compound is present in both the dormant and germinated cotyledons. There is no evidence, however, for its occur-

rence in either the roots or shoots of young plants or in other issues of the mature plant other than the pods.

Investigations are continuing on the DOPA-DOPA glucoside equilibrium in *V. faba*. The apparent lack of glucoside in the tissues could be due to a weakly active specific glucosylating enzyme (although other phenols are readily glucosylated<sup>2</sup>) or to a physical barrier between the enzyme and its substrate, L-DOPA.

### Lysosomal Enzymes in Experimental Encephalomalacia

Pappenheimer and Goettsch<sup>1</sup> described the symptoms of chick encephalomalacia produced by vitamin E deficiency and indicated that capillary thrombosis may be the primary cause of the observed ischaemic necrosis. Muscular dystrophy of vitamin E-deficient rabbits may be considered the counterpart of experimental encephalomalacia in chicks since both diseases can be produced by lack of dietary vitamin E.

The activities of a number of acid hydrolases were observed to increase several-fold in skeletal muscle of dystrophic rabbits<sup>2-5</sup>. It was found in this laboratory that a neuraminidase activity (*N*-acetylneuraminyl glycohydrolase), which releases sialic acid from neuraminyl lactose, increases several-fold in skeletal muscle, spleen, and liver of vitamin E-deficient rabbits which developed muscular dystrophy<sup>5</sup>. It was also found that this enzymatic activity is concentrated in the lysosomal fraction obtained by centrifuging liver homogenates according to a technique developed by De Duve *et al.*<sup>6</sup> for tissue fractionation experiments. The presence of lysosomes in brain cells has been demonstrated histochemically by Koenig<sup>7</sup>. An important property of lysosomal enzymes is that they exhibit little activity towards their substrates so long as they remain bound to the intact particles. Rupture of lysosomes within cells can cause solubilization and activation of the bound hydrolases and may play an important part in cellular autolysis, pathological necrosis and inflammation. Evidence for the existence of a neuraminidase activity (*N*-acetylneuraminyl glycohydrolase) in rat brain and other rat organs has been reported by Carubelli *et al.*<sup>8</sup>. Morgan and Laurel<sup>9</sup> demonstrated the presence of an enzyme activity in mammalian brains which releases sialic acid from the endogenous sialic acid-containing compounds within a pH range of 3.5 and 4.0. This report describes the distribution of neuraminidase in fractions of normal chick brain, and experiments which show the effects of encephalomalacia resulting from vitamin E deficiency on the total activity and the intracellular distribution of neuraminidase and other lysosomal hydrolases.

Encephalomalacia in chicks was produced by feeding a specially formulated diet deficient in  $\alpha$ -tocopherol (vitamin E) to one-day-old White Leghorn cockerels<sup>10</sup>. The control chicks received the same diet supplemented with vitamin E. Assays for the total activity of lysosomal enzymes require pretreatment with detergent substances such as

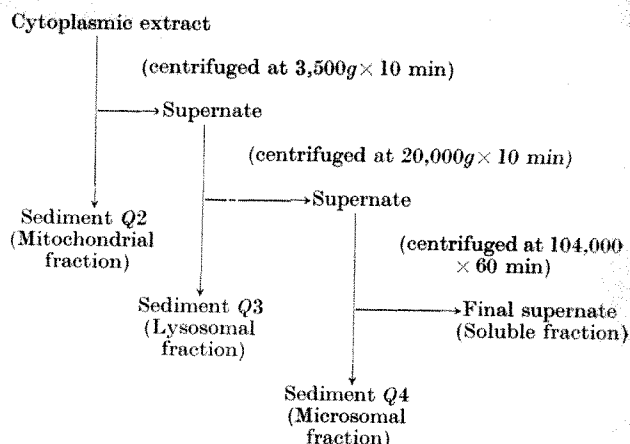

Fig. 1. Flow diagram of cytoplasmic extract fractionation

'Triton X-100' in order to activate the bound enzymes in the lysosomal particles. The total activities of several acid hydrolases were determined in brain homogenates of encephalomalacic and control chicks.  $\beta$ -Glycerophosphate phosphohydrolase (acid phosphatase) activity was determined according to a method described by De Duve *et al.*<sup>6</sup>. This enzyme is one of the original five acid hydrolases which have been identified by De Duve and co-workers as lysosomal enzymes. *N*-Acetylneuraminyl glycohydrolase (neuraminidase) activity was assayed by the method of Carubelli *et al.*<sup>8</sup> in which neuramin-lactose is used as the substrate.  $\beta$ -D-Glucuronide glucuronohydrolase ( $\beta$ -glucuronidase) activity was assayed by De Duve's modification<sup>6</sup> of a method by Fishman *et al.*<sup>11</sup> to permit measurement of total activity. Phenolphthalein glucuronide (Sigma Chemical Co., St. Louis, Mo.) was used as the substrate.

Intracellular components were sedimented by centrifuging brain homogenates according to a technique based on the procedures of De Duve *et al.*<sup>6</sup>. The homogenizing medium was 0.25 M sucrose containing 0.001 M disodium ethylenediamine tetraacetate (EDTA). Homogenization was accomplished by a single passage of the grinding tube upwards then downwards against the rapidly revolving pestle (about 1,000 rev./min) so that all the material had been forced above and then below the 'Teflon' part of the pestle once. The resulting slurry was centrifuged in the cold at 1,000g for 10 min. The sediment, which still contained a large number of unbroken cells in addition to nuclei, was re-homogenized by the foregoing procedure in the same quantity of medium used in the first homogenization and centrifuged at 800g for 10 min. The supernatants (cytoplasmic extracts) were combined and made up to volume to an equivalent of 100 mg tissue per ml. cytoplasmic extract. The sediment (Q1) constituted the nuclear and debris fraction. The cytoplasmic extract was further fractionated according to the scheme outlined here (Fig. 1) using a Spinco model L preparative ultracentrifuge to obtain three additional particulate fractions and the final supernatant. The supernatant solutions were carefully removed by aspiration. The fluffy layer on top of the lysosomal fraction was removed with the supernate to be recovered later with the microsomal fraction. The sediments were suspended in 0.1 M acetate buffer, pH 5.0, and re-homogenized to obtain the equivalent of 500 mg of original tissue per ml. of suspension. These suspensions were used to assay the total activity (free + bound) of acid phosphatase and neuraminidase in the isolated cytoplasmic fractions.

In the control chicks, the determination of acid phosphatase activity ( $\beta$ -glycerophosphate phosphohydrolase) demonstrates a distribution of activity in the cytoplasmic fraction which is typical of lysosomal enzymes (Table 1). The intracellular distribution of neuraminidase (*N*-

Table 1. DISTRIBUTION OF ACID PHOSPHATASE IN CYTOPLASMIC FRACTIONS OF ENCEPHALOMALACIC AND CONTROL CHICK BRAINS

$$\text{Relative specific activity} = \frac{(\text{percentage of total activity})}{(\text{percentage of total protein})}$$

Control chicks were fed the vitamin E-supplemented diet, encephalomalacic chicks received the vitamin E-deficient diet. The values are averages of three experiments.

Table 3. ACID HYDROLASES IN CHICK BRAINS

	Specific activity Controls (5)*	Specific activity Malacic (5)
Acid phosphatase	0.95 ± 0.06†	1.72 ± 0.08
β-glucuronidase	32.5 ± 2.8	156.6 ± 11.3
Neuraminidase	0.34 ± 0.02	0.77 ± 0.06

Specific activities are expressed as follows: acid phosphatase—μmoles orthophosphate hydrolysed per mg protein per h; β-glucuronidase—μmoles phenolphthalein hydrolysed per mg protein per h; neuraminidase—μmoles sialic acid released per mg protein per h. \* Number of experiments. † Standard error.

acetylneuraminyl glycohydrolase) in control chicks is shown in Table 2, where it is apparent that the enzymatic activity is present in the soluble and not only in the lysosomal fraction. The high relative specific activity noted in the soluble fraction may indicate the presence of a second neuraminidase activity. The heterogeneity of sialic acid-containing compounds in brain (gangliosides in particular) has been demonstrated by Svennerholm<sup>12</sup>, which suggests that more than one type of neuraminidase activity may be required in the metabolism of these substrates.

The results shown in Table 3 indicate a significant increase in the total activities of acid phosphatase, β-glucuronidase and neuraminidase in brain homogenates of vitamin E-deficient encephalomalacic chicks. The increased levels of acid hydrolases (lysosomal) enzymes in the free form in brain could conceivably contribute to brain degeneration by acting on their respective substrates. However, it could not be established that lysosomes had actually ruptured *in situ* before the appearance of encephalomalacic symptoms or brain necrosis.

Calculations of the relative specific activity permit an evaluation of how the activity is distributed within the cells in relation to the observed total activity of the homogenates. The distribution patterns of brain acid phosphatase (Table 1) and brain neuraminidase (Table 2) in encephalomalacia due to vitamin E deficiency reveal a reduction in the activity of the enzymes in the particulate fractions especially in the lysosomal fraction with a concurrent increase in the soluble fraction. These results may indicate rupture of lysosomes *in vivo* resulting in an increased solubilization of the bound hydrolases. It was demonstrated by De Duve *et al.*<sup>13</sup> that five lysosomal enzymes were released rapidly in liver tissues which were rendered completely ischaemic by ligation of the blood vessels. Van Lanker *et al.*<sup>14</sup> reported similar results with respect to β-glucuronidase and acid phosphatase in autolyzing mouse liver fragments.

The experiments demonstrate that the stability of lysosomal particles is decreased in vitamin E deficiency,

but it could not be determined if the partial solubilization occurred before the malacic process began. The total activities have also increased significantly in brain homogenates of encephalomalacic chicks and may be a reflexion of the increased number of phagocytes and other reticulo-endothelial system cells in the necrotic areas of the brain. Such cells, which play an important part in pathological necrosis, have been shown to be rich sources of lysosomal hydrolases<sup>15,16</sup>.

## Zone Electrophoresis of Human Parotid Saliva in Acrylamide Gel

THE zone electrophoresis of human parotid saliva proteins has been carried out with a variety of supporting media, including filter paper, cellulose acetate, agar gel and starch gel, with separations usually of from five to twelve fractions<sup>1-8</sup>. In a comparative investigation of these media, D'Silva and Ferguson<sup>7</sup> obtained their most satisfactory results with a combination of cellulose acetate and starch gel, thereby separating seventeen protein components from the parotid saliva of one subject. The present report concerns an examination of acrylamide gel as another medium for the zone electrophoresis of parotid saliva proteins. Preliminary experiments with acrylamide-gel strips have yielded protein patterns in which twenty or more fractions could be visually distinguished when the electrophoresis was carried out in 0.1 M tris-EDTA-boric acid buffer at pH 9.0. The tests were conducted on individual collections of parotid saliva from three subjects and on pooled collections of parotid saliva from several subjects. Fig. 1 shows the electrophoresis pattern of a sample of the pooled parotid saliva. Under the conditions of the experiment, more than half the staining components migrated anodically with generally better resolution than is evident for the cathodically-migrating components. Although disk electrophoresis on acrylamide gel has been widely used in investigations of serum proteins, gel strips were used for this investigation of parotid saliva in order to obtain the complete pattern of staining components, migrating both anodically and cathodically, for each electrophoresis run. Gel strips also permit the handling of larger quantities of protein than is feasible with disk electrophoresis, should recovery of particular fractions be desired. Salivary amylase, a troublesome factor in the starch-gel electrophoresis of saliva proteins, does not attack acrylamide gel.

Fig. 1. Acrylamide-gel electrophoresis of pooled parotid saliva. O, origin; A, anode; C, cathode

The procedure for gel-strip preparation was adapted from the methods of Raymond *et al.*<sup>9</sup> and of Ornstein and Davis<sup>10</sup>. A 5.133 g sample of acrylamide and methylenebisacrylamide in 97.4:2.6 (w/w) proportions was dissolved in the *tris*-EDTA-boric acid buffer with 0.06 ml. of *N,N,N',N'*-tetramethylethylenediamine to a final volume of 98 ml. Two ml. of a freshly-prepared 5 per cent (w/v) solution of ammonium persulphate in the buffer was added to initiate polymerization and the resulting mixture was poured into a 'Plexiglas' mould, designed to produce a 265 × 50 × 3-mm gel strip. Polymerization was accomplished after about 30 min at room temperature.

The parotid saliva from U.S. Naval recruits 17-23 years of age was collected by paraffin mastication, using modified Lashley cups<sup>11</sup>. Individual or pooled collections of the saliva were dialysed against deionized water at 4° C to remove inorganic salts and were lyophilized. For electrophoresis, each lyophilized preparation was dissolved in the *tris*-EDTA-boric acid buffer to a final concentration of 15 per cent (w/v). After an incision of about 35-40 mm was made across the midpoint of a gel strip, a 35 × 2-mm section of filter paper (Schleicher and Schuell No. 470) was saturated with the protein preparation (c. 10-11 mg dry wt.) and positioned in the incision. The gel strip, sandwiched between 'Parafilm' sheets, was then placed in a horizontal water-cooled electrophoresis unit (Research Specialties Co., Richmond, Cal.) and electrophoresis was carried out for 2.5 h at a field strength of 8-9 V/cm strip length and a current of 4 m.amp/cm strip width. Electrical contact between the gel strip and the bridge buffer (0.05 M veronal, pH 8.6) was maintained by paired paper wicks (Schleicher and Schuell No. 470). The strip was stained for 45 min with 1 per cent amido black 10B in a 5:1:5 methanol, glacial acetic acid, water mixture. Excess stain was removed electrophoretically by the method of Ferris<sup>12</sup>, using 3.75 per cent acetic acid.

Immunochemical investigations<sup>13,14</sup> have provided evidence that parotid saliva contains serum proteins as well as proteins of apparently intrinsic salivary origin. The present interest in acrylamide-gel electrophoresis for investigating serum proteins arises largely from the influence of specific pathologies on the electrophoretic patterns obtained by this method. Acrylamide-gel electrophoresis would likewise appear to be a promising means of exploring variations in patterns of parotid

saliva protein that may accompany disturbances in an individual's metabolism.

## PHYSIOLOGY

### 5-Hydroxytryptamine Receptors and Synaptic Transmission in Molluscan Neurones

Welsh and Moorhead<sup>1</sup> found large amounts of 5-hydroxytryptamine (5-HT) in the nervous system of different classes of molluscs and postulated its possible role as a transmitter. More recently the presence of 5-HT in land-snail nervous tissue was confirmed by Kerkut and Cottrell<sup>2</sup> and by Cardot and Ripplinger<sup>3</sup>. The interest of this finding was stressed by Ersparmer<sup>4</sup>, who pointed out that "a thorough study of the 5-HT in the nervous tissue of Molluscs may offer a key to a better understanding of the function of the amine in the brain of Vertebrates".

Various effects of 5-HT on gasteropod neurones are observed when whole ganglia are perfused<sup>5</sup>. Since some of these effects may result from interneurone interference, the present investigation is mainly concerned with the local application of the amine to individual neurones. 5-HT was injected by iontophoresis on the somatic surface membrane devoided of synapses of the monopolar central neurones of the Argentine land-snail *Cryptomphallus aspersa*. Neurones were impaled with single- or double-barrelled micro-electrodes and the bioelectrical activity recorded with a standard d.c. set. 5-HT was injected as a cation from micropipettes of 25-30 MΩ resistance filled with a 0.15 solution of 5-HT creatinine-sulphate solution, at a pH of 3.2. Sometimes a braking current was necessary to avoid desensitizing effects of drug leakage. The position of the microelectrode was tested by direct observation with a stereoscopic microscope and also by introducing the injecting microelectrode into the neurone, passing a square pulse to confirm its intracellular position, and then pulling out again the micropipette. In some cases, when a double-barrelled injecting micro-electrode containing acetylcholine (ACh) in one barrel and 5-HT in the other was used, effects obtained with ACh confirmed the extracellular location of the micro-electrode in absence of 5-HT effects.

Only a limited number of cells are responsive to 5-HT iontophoretic injection; this is in contrast to the response of a large number of cells, evoked by drug perfusion of the whole nervous system. These cells belong to a group of neurones which, besides excitatory post-

Fig. 1. Left row: intracellular recordings belonging to the same CILDA neurone. *A*, Ionophoretic injection of 5-HT on the somatic membrane (arrows) provokes depolarization and excitation of the cell. *B* and *C*, Repeating the injections at two different short intervals the effects are markedly diminished due to desensitization phenomena. *D* corresponds to a desensitization curve obtained in the same cell, hyperpolarizing it through a second intracellular microelectrode. The relation of the effect of successive injections on the membrane potential level compared with the initial one ( $\frac{E_a}{E_m} = \frac{\text{effect of injection}}{\text{initial or maximal effect}}$ ) was plotted against the injection interval in seconds. It is possible to appreciate that an interval of 34 sec is necessary to come back to the maximal effect of injections ( $\frac{E_a}{E_m} = 1$ ).

synaptic potentials (EPSP), show a peculiar inhibitory input first described by Tauc<sup>6</sup> as 'inhibition of long duration' (ILD). This inhibition is characterized by a long-lasting hyperpolarizing wave evoked by orthodromic stimulation and generally preceded by an excitatory burst. Gerschenfeld and Tauc<sup>7</sup> recognized this group of neurones with the conventional name of CILDA (cells with ILD). These neurones are characterized by the presence on their membrane of specific 5-HT receptors. 5-HT micro-injections passing currents of 10–50 nAmp during 0.5–1 sec produce transient depolarization and excitation of CILDA neurones (Figs. 1*A* and 2). Repeated micro-injections cause intense desensitization of the receptors

(Figs. 1*B* and *C*) similar to those observed, at the cellular level, in ACh receptors of both vertebrate muscle endplate<sup>8</sup> and *Aplysia* neurones<sup>9</sup> and in glutamate receptors of snail neurones<sup>10</sup>. Fig. 1*D* corresponds to a desensitization curve showing that an interval of about 40 sec is necessary to obtain maximal effects with two successive injections.

It is also possible to show that the ionophoretic injection of 5-HT only affects a restricted area of the neurone membrane, drug diffusion being negligible. In Fig. 3*C* the curve *a* represents a dose-response curve in which the dose is represented by the logarithm of the injected current in nAmp. Since the curve obtained is similar to a Langmuir isotherm and the microelectrode behaves as an 'ohmic' resistance, the plateau of the curve represents saturation of receptors, that is, the injection is recruiting a limited number of receptors from a restricted patch of the membrane.

5-HT receptors of CILDA neurones may be blocked by isomolar concentrations of lysergic acid diethylamide (LSD 25) or its derivatives and morphine (Fig. 2), that is, they share properties of both *D* and *M* receptors in other preparations<sup>11</sup>. Bromolysergic acid (BOL 148) appears to be much more active than LSD 25. All these drugs block 5-HT receptors reversibly and the same action is also shown by atropine and chlorpromazine. On the other hand, tryptamine, cyproheptadine and dibenamine block the receptor in an irreversible manner.

Relatively high concentrations (more than  $5 \times 10^{-3}$  M) of SKF trans-385 B and iproniazid, two well-known inhibitors of monoamino-oxidase (MAO), block the receptor response. SKF trans-385 B in lower concentrations enhances the effect of 5-HT micro-injections, but it is not clear whether the drug mimics and/or reinforces the 5-HT effect, or actually causes an inhibition of MAO which is located in the mitochondria<sup>12</sup>.

If 5-HT behaves as a true synaptic transmitter it is to be expected that it would alter the cell membrane conductance. Indeed, 5-HT exclusively affects the membrane conductance of CILDA neurones, increasing it to twice its value (Fig. 3*A*). This effect is highly specific because the amine does not alter the membrane constants of other types of cells (Fig. 3*B*) in the same ganglia.

Fig. 2. Intracellular recordings of CILDA neurones ionophoretically injected on their membrane with 5-HT, using an injecting current of 75 nAmp during 1 sec. The injection microelectrode was filled with a solution of 5-HT creatine-sulphate 0.15 M at a pH of 3.2. *A1*, Control injection; *A2*, the same injection when bromolysergic acid is diluted in the bathing Ringer; the effects of the injection are blocked in spite of the slight depolarization provoked; *A3*, the effect of the injection returns when the blocking drug is removed from the bath. *B1*, Control ionophoretic injection of 5-HT; *B2*, blockade of the injection by the presence of morphine chloride in the cell environment; *B3*, the effect of morphine is reversible; effects of 5-HT injection return after washing. Concentrations used of both BOL 148 and morphine were  $10^{-4}$  M.

Fig. 3. In A, a CILDA neurone was impaled with a double-barrelled microelectrode. Square pulses of inward current were passed between an indifferent lead and one of the barrels in order to measure the membrane resistance. Application of 5-HT by perfusion to a cell of the type H in B did not affect the membrane resistance measured with the same technique. C, Drug-response curves of CILDA neurones to 5-HT ionophoretic injection. The cell was impaled with a double-barrelled microelectrode and artificially hyperpolarized; the membrane potential variations produced by the injections were taken as the measures of response. The abscissa correspond to the dose represented by the logarithm of the injecting current in nAmp. The ordinate is represented by the relation between the response to a determined dose ( $E_a$ ) and the maximal response obtained ( $E_m$ ). Curve a corresponds to a control dose-response curve. Curve b was obtained in the presence in the neurone environment of a  $2.5 \times 10^{-4}$  M solution of BOL 148 and curve c in the presence of a  $2.5 \times 10^{-4}$  M solution of BOL 148.

Application of the approach of the Nijmegen group<sup>13,14</sup> allows an analysis of the mechanism of blockade of CILDA neurone 5-HT-receptors by BOL 148. Comparing the control dose-response curve (Fig. 3C, curve a) obtained by injecting 5-HT on CILDA receptors with those obtained in the presence of diluted solutions of BOL 148 (Fig. 3C, curves b and c) it is possible to demonstrate that they correspond to a family of Langmuir isotherms presenting identical shape and slope and with a  $pA_2$  value of 8. These results may be interpreted as an indication that blockade by bromolysergic acid is due to an actual competitive mechanism between the antagonist and the agonist for the same receptor site.

In conclusion, the high content of 5-HT in snail ganglia, also confirmed for *Cryptomphallus aspersa*<sup>15</sup>, the presence of enzymes capable of synthesizing<sup>16,17</sup> and inactivating<sup>18</sup> 5-HT, the specific effects of the amine on the CILDA membrane conductance and the presence of specific 5-HT receptors on the membrane of the same neurone type fill some of the criteria required to consider a substance as a synaptic transmitter. Specific blockade of 5-HT receptors by LSD derivatives, first described by Gaddum<sup>19</sup> and confirmed at the cellular level in extra-synaptic receptors of CILDA neurones, provides an important clue for the investigation of 5-HT receptors at the synaptic level. The recent finding<sup>7</sup> that BOL 148 blocks excitatory postsynaptic potentials rather specifically in CILDA neurones without affecting the inhibition of long-duration input points toward the probable existence of 5-HT receptors at the postsynaptic membrane of these neurones and suggests, in addition to the other findings, that 5-HT may be the natural excitatory transmitter for CILDA neurones. However, more information regarding 5-HT synaptic receptors and 5-HT release and inactivation in molluscan nervous tissue is necessary to confirm this hypothesis.

### Perception of Contours in the Central Fovea

Hubel and Wiesel<sup>1</sup> have shown that many neurones in the cat's striate cortex respond specifically to short black or white lines at particular orientations. A series of experiments by me, using psychophysical methods, supports the hypothesis that similar 'filter' units (FF) are to be found in the human visual system.

Various properties of these FF can be inferred from the results, concerning both permanent structures in the system and their dynamic function, and it will simplify the exposition if these hypotheses are stated first. Alternative hypothetical properties could, of course, be invoked, but the following are the most economical that are found which are consistent with all the data:

(1) Each F responds to a range of presentation orientations ( $\theta$ ); the response characteristic is bell-shaped and has extensive tails.

(2) FF vary in selectivity. Those tuned to orientations near the horizontal and vertical are the most selective.

The most selective FF are centred around two directions which differ by small angles (denoted by  $\Delta H$  and  $\Delta V$ ) from the horizontal and vertical respectively;  $\Delta H$  and  $\Delta V$  are generally not zero, nor greater than  $15^\circ$ , and vary from place to place in the field.

(3) Most FF receive inputs from both eyes.

(4) Integration of FF responses is achieved by mutual inhibition, which takes a matter of seconds to reach a steady level.

When a short-line stimulus causes FF to respond, all but a few are inhibited completely when the inhibition has had time to reach a certain level, and these respond in a proportion which determines the angle seen. If the line is sufficiently short, all but two will eventually be inhibited completely.

(5) The inhibition between FF is subject to adaptation. The sensitivity of any particular F is proportional to the average level of inhibition it has received over a period. Its own output of inhibitory signals is proportional to its present activity<sup>2</sup>. The storage period supporting this adaptation is a matter of weeks.

These properties engender some unexpected consequences, and at the same time are supported by a number of independent findings. Hypotheses (1) and (3) are in line with Hubel and Wiesel's results. Hypothesis (2) is supported by experiments which show that grating acuity<sup>3</sup>, fine-line acuity<sup>4</sup>, and vernier acuity<sup>5</sup> all vary according to orientation of the test lines; this variation has never been satisfactorily explained. My experiments show that acuity for orientation of a short line is also better in the horizontal and vertical directions than at  $\pm 45^\circ$ .

Hypotheses (1), (2) and (4) in combination lead to a surprising result. When a short line is presented for a few milliseconds only, there is no time for inhibition to be set up; consequently, any of a wide range of FF may make an appreciable response (on account of the substantial tails of the response characteristic). The resulting variation of apparent slopes is much greater than for longer exposures. This variation was observed: if a line subtending  $6'$  arc at the eye is flashed every few seconds, it is seen quite clearly at a different inclination every time; the variation is occasionally as great as  $\pm 30^\circ$ .

These errors are not normally distributed. This finding led to postulate (2) here. If  $\theta$  is, say,  $+10^\circ$  from the horizontal, an erroneous appearance is much more likely to arise from one of the less selective FF peaking between  $+0^\circ$  and  $+20^\circ$  than from one of the more selective FF peaking between  $0^\circ$  and  $+10^\circ$ . Other ranges of FF can be considered in the same way; the net result is that the mean apparent slope of a short flashed line is biased away from the horizontal (and similarly at the vertical). This phenomenon has also been observed; the results might be described as a 'stretching' of the scale of apparent orientation. In the neighbourhood of the horizontal or vertical the 'stretch factor' may be as high as 2.0. As

Fig. 1. Biases of perceived orientation of a short line, as a function of presentation angle and duration of exposure

interpreted in hypothesis (2), this is not an actual stretching of the metric of visual space; it is just a statistic of the error distribution. It is the distribution of mean appearance that is 'stretched', while each individual F has its peak response in proper correspondence with  $\theta$ .

When  $\Delta H \neq 0$ , there will be a mean bias at the horizontal itself. Such biases are observed, and range up to  $\pm 5^\circ$ . They vary according to the position of the line in the fovea, in an arbitrary way. Corresponding points in left and right foveas show correlated biases:  $r = 0.8$ . This provides strong support for hypothesis (3).

When the presentation period is long enough for inhibition to build up, all these effects are subject to systematic changes.

Hypothesis (5) can be elaborated: all the FF in any one small region form a dynamically stable system which in effect assigns apparent orientations to particular combinations of F-responses. It has been shown how the frequency distribution of F-responses precipitates biases of mean apparent orientation. When the F-responses are integrated, this mean bias is seen, whereas with single flashes it is a statistic of the error distribution. The adaptation suggested in (5) will continually adjust biases so that over a period the frequency distribution of apparent inclinations is uniform. This statistic is true of images chosen at random from a visual environment, so if the system integrates over a reasonably long period, the resulting scale will be satisfactory. I have suggested<sup>6</sup> that the metric of visual space is continually adjusted by a similar mechanism, which provides that contour-curvatures and contour-spacings shall be uniformly distributed throughout visual space.

Now, in normal viewing, saccades occur at intervals of order 0.5 sec (ref. 7). The adaptation equilibrium will therefore be adjusted so that there is a satisfactory scale of orientation for viewing durations of this order. For shorter viewing periods, the inhibition will not cancel the biases engendered by the selectivity distribution, and for longer periods the inhibition will over-compensate and reverse the biases found with flash stimulation. The bias does not reach a steady level for a second or two. Ratliff *et al.*<sup>8</sup> have shown that lateral inhibition takes a similar period to reach a steady level in the eye of *Limulus*. It is, in any event, desirable that inhibition should have a longer time-constant than excitatory response, if its purpose is to stabilize or integrate the latter.

This reversal of bias is observed, and was the principal reason for invoking (5). Fig. 1 illustrates how the pattern of biases changed as a function of exposure time for one subject. This transition has been mapped in detail for one subject only, but results for the two extreme durations

have been obtained for three subjects, and all showed the same net pattern of change. Details of the experiment were as follows. A short bright line subtended  $6' \times 1.0'$  at the eye, and was presented at 7-sec intervals against an illuminated background. The brightness of the short line was at that level which gave optimal acuity, which was first established for each exposure time. The subject (D. P. A.) adjusted the slope between flashes until satisfied that it matched that of a long thread near by, which was at one of 14 inclinations. This matching was repeated 17 times to give the mean bias ( $\bar{x}$ ); the *S.E.* of  $\bar{x}$  ranged between  $0.15^\circ$  and  $0.3^\circ$  (within-run), but  $\bar{x}$  is also subject to drift between runs which will affect reliability, since the experiment took several days. Each inclination of the comparison thread was used for 6 successive runs at the different exposure times. The sequences of these 6 runs and of the 14 comparison inclinations were randomized.

All measurements are in degrees, measured clockwise from the vertical for  $\theta$ , with  $\bar{x}$  measured from  $\theta$ . The graphs show the 'stretch' effects already described. Gradients around the horizontal, vertical and  $\pm 45^\circ$  directions undergo systematic changes as a function of exposure duration.

A further indication that F-outputs are subject to adaptation can be seen in the last two lines of Fig. 1, which show the  $\theta$ -bias function for continuous exposure, and the same function six months earlier. Although the general shape of the function is the same in the two cases, the actual values of bias differ considerably. This drift is co-ordinated: the biases at neighbouring orientations have drifted by similar amounts. Similar drifting has been found to affect the biases depending on the position of the stimulus line in the field; in this case, the drift was co-ordinated spatially over a foveal region  $40'$  square.

This drifting is evidently held within limits of some kind, or the pattern of the results would change as well as the actual values. The adaptation hypothesis (5) is an economical explanation of these phenomena. Such a mechanism has the advantage that the nervous system does not have to encode exact values of orientation, which frees it from a difficult engineering problem. So long as the sequence of orientation values is preserved reasonably well throughout the transmission lines, the system can supply a satisfactory scale of perceived orientation at the receiving end.

I thank Prof. D. M. MacKay, Dr. H. B. Barlow and Dr. J. P. Wilson for their advice and comments.

### True Venous Pulse Wave

THE classical jugular phlebogram (JP) is a composite record of arterial and venous pulsations. Mackenzie<sup>1</sup> noted that if the carotid arterial pulse wave could be subtracted from the JP we would have what he called 'the true venous pulse wave'. He was, however, unable to obtain such a record experimentally.

An approach to this problem was made as follows. Pulse recording elements were placed, first, in the position where classically the JP is recorded (in the angle formed by the origin of the right sternomastoid muscle and the upper and inner margin of the clavicle) and, secondly,

over the right carotid artery as high as was feasible in the neck. A technique was devised to ensure the temporal alignment of the carotid pulsations from both recording sites. The magnitude of the pulsations was also balanced. The subject was supine on a tilting table  $10^\circ$  head-up. These two sets of pulsations were recorded through a differential gauge made by Statham, Puerto Rico (P 23 H, No. 113). Fig. 1A shows a typical record made with a Grass Polygraph. Reading from the top the records are ECG, jugular phlebogram, true venous pulse (TVP) and right carotid. The differential record of the TVP is obtained by subtracting the carotid record (line 4) from the JP (line 2).

Fig. 1

The most obvious difference between the JP and the TVP records is the change in the 'c' wave. This may be absent. If it is present it is small and coincident with the early part of the anacrotic limb of the carotid pulsation (see Fig. 1B). The 'a', 'v' and 'h' waves are superimposed on a rising base line which starts at the bottom of the X<sup>2</sup> wave and rises to the summit of the 'a' wave. This base line in the JP is usually horizontal. Another feature of the negative wave X<sup>2</sup> is that it is more prominent, with a rapid descending limb from the summit of 'a'.

## Uptake of Formalin by Brain Tissue from Dogs killed at various Stages of Development

EARLIER work<sup>1</sup> with fresh canine brains has shown that there is a linear increase in the dry matter content from birth to 6 weeks of age (10 per cent to 19 per cent) and then a more gradual maturation to the adult level of 20 per cent. A rapid increase in brain volume up to 6 weeks of age was also found.

Histological examination of the occipital and frontal cortex revealed changes in cell density with age<sup>2-4</sup>, there being a great reduction in cell density from birth to 6 weeks of age (250-60 cells per unit area) followed by a gradual reduction to the adult density of 40-45 cells per unit area.

Fourteen inbred Beagle dogs ranging from birth to adulthood were used in the present investigation; under deep urethane anaesthesia seven dogs were perfused with paraffinized normal saline followed by formalin; the brain matter was removed from the brain, which was then immersed in formalin for 4 weeks. After this time the brain was dissected and the parts were weighed before and after maceration and desiccation for 5 days in a drying oven. The parts consisted of medulla and pons (up to the superior colliculi) and cerebral cortex (excluding olfactory lobes). After desiccation the remaining weight of each part was determined and expressed as a percentage of the original formalin-fixed weight before desiccation (Fig. 1). Even controls of corresponding ages were similarly treated, with the omission of formalin perfusion and fixation.

Fig. 1. Percentage of dry matter in different parts of the brain of the dog at different ages and after formalin fixation. ●, Medulla; ▲, cerebrum. Broken lines, formalin fixed

It was found that the percentage of dry matter was least at birth and increased gradually with age. Some evidence of caudocephalad encephalization was found in various parts of the brain, the most caudal region having the greatest dry matter content.

It would appear that the amount of formalin taken up by central nervous tissue is a function of cell size and changes in cell density with age. In young specimens where the cell density is greatest there is consequently a reduction in the intercellular space, and because the average size of the neurone does not reach adult dimensions until 4 weeks of age (neuroblastiform at birth in the cerebrum), the interperikaryal space is consequently less in younger specimens<sup>4</sup>. The reduction in dry matter content following fixation is at present under investigation; it has been suggested that phospholipids are leached during fixation.

Calculation of the dry matter content after desiccation of fresh and formalin-fixed specimens therefore gives an indirect estimate of the intra- and extra-cellular content of the brain which can be correlated with other aspects of

post-natal development. Higher dry matter percentages are found in the more caudal parts of the brain in accordance with greater aggregation and packing of neurones and nerve tracts as compared with the cytoarchitectonics of the cerebral cortex<sup>5,6</sup>.

These findings were correlated with previous data on the developing canine brain. The percentage dry matter of formalin-fixed tissue was directly correlated ( $P < 0.01$ ) with cell density and a 10 per cent loss in the percentage dry matter content of fresh brain predictable after fixation.

## Calcium Exchangeability in Frog Sartorius Muscle during Potassium Depolarization

THE release of calcium from the membrane or from endoplasmic reticulum is regarded as the main process in the mechanism provoking muscle contraction. The system of membrane control of contractile activity in the fast muscle fibres has several properties for which similar terminology was proposed as for the membrane control of Na conductance<sup>1</sup>. In this work some properties of the Ca-releasing system were examined by using <sup>45</sup>Ca and the results are discussed in terms of membrane control of Na conductance.

Sartorii of the frog *Rana temporaria* were used. The experiments were carried out in Ringer's solution containing: NaCl, 115 mM; KCl, 2.5 mM; CaCl<sub>2</sub>, 1.8 mM; Na<sub>2</sub>HPO<sub>4</sub>, 2.15 mM; NaH<sub>2</sub>PO<sub>4</sub>, 0.85 mM. High-CaCl<sub>2</sub> Ringer's was made without phosphates. When increasing the K concentration the corresponding amount of KCl was substituted for NaCl. One of the pair of sartorii of each animal was used as an experimental muscle; the other as a control. Two series of experiments were carried out. In the first series the control muscle was exposed for 15 min to <sup>45</sup>Ca Ringer's solution (RS). The experimental muscle was exposed for 5 min to <sup>45</sup>Ca RS and for 10 min to <sup>45</sup>Ca RS with high K. The muscles were washed four times for 5, 10, 25 and 50 min in non-radioactive RS to remove <sup>45</sup>Ca from the extracellular space and from the superficial binding sites of the fibres<sup>2</sup>. They were then ashed and the radioactivity was counted. In the second series the control muscle was immersed for 40 (or 10) min in non-radioactive RS, then the <sup>45</sup>Ca RS was applied for 15 min. The experimental muscle was exposed for 40 (or 10) min to non-radioactive high-K RS, then the high-K <sup>45</sup>Ca RS was applied for 15 min. To prevent twitching, 10<sup>-4</sup> M cocaine was added in all solutions.

In preliminary kinetic experiments it was found that the estimation of Ca influx in the sartorii of *Rana temporaria* on the basis of the slow component does not represent the real exchange of cellular Ca. For this reason the changes in Ca movements were evaluated only as the changes in Ca exchangeability. The values in Fig. 1 concerning the values between 20 and 50 mM K do not, therefore, represent quantitative relation between Ca exchange and K concentration.

The changes in Ca exchangeability at different values of depolarization are shown in Fig. 1. A big increase in Ca exchangeability was found both at the beginning of depolarization and after 40 min depolarizing with 15-20 mM K. At greater depolarization a big increase in ex-

Fig. 1. Ca exchangeability at different values of K depolarization. Radioactivity in control muscles is taken as 100 per cent. Open circles, Ca exchangeability at the beginning of depolarization; filled circles, after 40 min.

changeability was found only at the beginning of depolarization. Maintained increase in Ca influx in 20 mM K RS was reported also by Bianchi and Shanes<sup>3</sup>.

In further experiments the influence of procaine and  $\text{CaCl}_2$  on Ca exchangeability was investigated (Fig. 2). It was found that both procaine and  $\text{CaCl}_2$  suppressed Ca exchangeability at low depolarization (20 mM K, that is, about 50 mV of membrane potential). At a higher level of depolarization (40 mM K, that is, about 30 mV) their effect was found to be different. Procaine still favours the suppression of exchangeability.  $\text{CaCl}_2$ , on the other hand, does not act in the sense of suppression, but causes a long-lasting increase of exchangeability. The same effect as for procaine was found for phenobarbital and physostigmine<sup>3</sup>. It must be mentioned that the concentrations of the drugs and  $\text{CaCl}_2$  used in our experiments do not substantially influence the sensitivity of the muscle fibre membrane to K depolarization<sup>4</sup>. An inhibitory effect of procaine on Ca influx induced without depolarization by caffeine was reported by Feinstein<sup>5</sup>.

Summarizing our findings, we think that the terminology used for the control of Na conductance in excitable tissues can be accepted. We suppose that the system releasing Ca from its bound state is activated for a long period when the membrane is depolarized to about 50 mV. At higher depolarization values the process of activation lasts for a shorter period and is followed by inactivation of the system. The time-course of these processes seems, however, to be much slower than those governing Na conductance.

The experiments with procaine and  $\text{CaCl}_2$  strongly support the use of terms accepted for Na conductance.

Fig. 2. The effect of procaine and  $\text{CaCl}_2$  on Ca exchangeability at different values of K depolarization. Radioactivity in control muscles is taken as 100 per cent. The exposure to  $^{45}\text{Ca}$  is described in the text. In experiments with high  $\text{CaCl}_2$  both control and experimental muscles were exposed to 20 mM  $\text{CaCl}_2$ .

On the basis of electrophysiological examination, it is supposed that at low depolarization values both procaine and  $\text{CaCl}_2$  decrease Na conductance<sup>6-9</sup>. At higher values of depolarization the effect of these two compounds is different. Procaine favours inactivation of Na conductance, while  $\text{CaCl}_2$  favours activation. It seems that a similar mechanism of the action of procaine and  $\text{CaCl}_2$  on the Ca releasing mechanism can be inferred from our experiments.

The effect of  $\text{CaCl}_2$  on the release of Ca agrees very well with the effect of  $\text{CaCl}_2$  on the contractile properties of the fast frog muscle fibres observed by Pausching and Brecht<sup>10</sup>. These authors state that extracellular Ca increases the duration of K contracture caused by the prolonged activation of the Ca-releasing mechanism.

The results presented in this communication and those reported earlier<sup>4</sup> also suggest that the extra oxygen consumption caused by K depolarization might be directly connected with the increase of free Ca in the muscle fibres.

### A Possible Cytological Basis for the 'R' Membrane in the Vertebrate Eye

THE 'R' membrane was the name coined by Brindley for a hypothetical retinal barrier whose penetration by a microelectrode advancing from the vitreous chamber results in a marked drop in electrical resistance and decrease in capacitance. Later, Tomita, Murakami and Hashimoto<sup>2</sup> found that this barrier could be demonstrated in eyes from which the retina was removed, thus placing the barrier behind the retina either at the level of the pigment epithelium or at Bruch's membrane. This was afterwards confirmed by Brindley<sup>3</sup>. Since the membrane of Bruch appears to be a substantial structure in light microscopy, it was a likely candidate for the 'R' membrane. Electrode marking methods employed by Brown and Tasaki<sup>4</sup> gave results compatible with this hypothesis and ruling out the retina although in fact no clearly marking Bruch's membrane as distinct from the pigment epithelium. Cohen<sup>5</sup>, using electron microscopy cast doubt as to the role of Bruch's membrane in this phenomenon by pointing out that Bruch's membrane consisted of the basement membranes of the pigment epithelium and choroid capillaries together with a layer of loosely interwoven connective tissue. Since there is basement membrane at the retinal-vitreous junction where no electrical change of a comparable type is noted it seemed unlikely that Bruch's membrane had the requisite structure for significant electrical resistance.

Two other potential barriers are the external limiting 'membrane' and Verhoeff's 'membrane'. These names respectively designate the lines of terminal bars between the receptors and glial cells of Müller in the case of the external limiting 'membrane' and between the cells of the pigment epithelium in the case of Verhoeff's 'membrane'. These terminal bars are structures of presumed adhesive function and in nervous tissue occur at the surface junctions of all cells facing on the vertebrate cerebrum.

intricles both embryonically<sup>8,9</sup> and in the adult<sup>10</sup>. Since the cavity of the optic vesicle is cerebral ventricle and since the space between the external limiting 'membrane' and Verhoeff's 'membrane' is a persistence of this cavity, it is not surprising that terminal bar systems occur here. Previous considerations of the possibility that these structures formed the basis of the 'R' membrane phenomenon were based on the assumption that the external limiting 'membrane' and Verhoeff's 'membrane' were structurally identical. As the external limiting 'membrane' is a retinal structure and as the 'R' membrane lies behind the retina, it followed that an identical structure in both the pigment epithelium and retina could be ruled out. However, recent examination of the terminal bar systems in these two 'membranes' shows that they are not identical and that they differ significantly in an important structural detail. Moreover, they differ in a direction suggesting that the movement of ions between cells of the pigment epithelium alone might be restricted.

The vitreal chambers of eyes of anaesthetized (hypothermia) macaque monkeys were perfused with 5 ml. of a 5 per cent glutaraldehyde solution in Earle's balanced line (pH 7.4) and then enucleated. The anterior segment was removed and the rest of the eye submerged in fixative. While submerged the sclera was loosened with a spatula and cut free. After an hour's fixation the tissue was used briefly in the buffered Earle's saline and re-fixed in 2 per cent osmium tetroxide in the same buffer for 1 h, then dehydrated, embedded in epoxy resin and sectioned. The sections were stained with lead hydroxide and photographed with an RCA-3F electron microscope.

Fig. 1 shows the junction of two cells of the pigment epithelium at their inner (vitreal) aspect. After the terminology of Farquhar and Palade<sup>11</sup>, the junctional specializations observed consist of a tight junction or zonula occludens (zo) and sclerad to this a region of wider gap designated as a zonula adherens (za). Desmosomes or maculae adherens occur elsewhere between these membranes and are not illustrated here. Inasmuch as mic fixation generally shows a single dark line representing the inner or cytoplasmic line of unit plasma membrane structure<sup>12</sup>, and since the distance between the dark lines of the tight junction is 145 Å, the intercellular space can be regarded as virtually non-existent at the tight junction. Since this represents a section of what is continuous 'seal' between the edges of the inner faces

Fig. 2. The junctional area of the inner segment of a rod (r) and two glial cells of Müller (m) showing only a zonula adherens (za) ( $\times 46,900$ ).

of the cells of the pigment epithelium, the significant movement of ions and molecules across the inner face of the pigment epithelium may perhaps be confined to movements through the cell rather than around them. On the other hand, as shown in Fig. 2, the homologous junctions between the cells of Müller and the receptors, or between cells of Müller, fail to have tight junctions and show zonulae adherens structure only, the narrowest intercellular gap being of the order of 200 Å. Kuffler and Potter<sup>13</sup> have recently emphasized the significant part that such narrow intercellular clefts may play in movements of substances in the central nervous system. Thus for ion movements, only the tight junction of the pigment epithelium seems to constitute an adequate barrier to explain the 'R' membrane resistance. The 'R' membrane capacitance would follow from the extensiveness of cell surfaces in the pigment epithelium due to the long processes of the pigment cells which interdigitate with the receptor outer segments. The tight junctions of the pigment epithelium probably contribute significantly to the blood-ocular barrier which, on the basis of the extent of dye penetration, Rodriguez-Peralta<sup>14</sup> placed at the inner face of the pigment epithelium. The variations of terminal bar structure exhibited here suggest that such variations may occur elsewhere in the central nervous system and possess physiological significance.

### Evidence for the Fenn Effect in Skeletal Muscle exposed to Low $pO_2$

FENN<sup>1</sup>, and later Hill<sup>2</sup>, showed by heat measurements the isolated frog sartorius muscle liberated extra energy in proportion to the mechanical work done by the muscle during contraction ('Fenn effect'). More recently, analysis of the breakdown of high-energy phosphates also revealed that more energy is utilized by a contracting sartorius muscle, which is allowed to shorten against a load (isotonic contraction), than by a muscle which is not allowed to shorten (isometric contraction)<sup>3,4</sup>.

Efforts to establish the presence of the Fenn effect by measuring the oxygen consumption of muscles contracting isotonically vs. isometrically have not been in agreement. Fischer<sup>5</sup> found that when the work was near maximal extra oxygen was consumed during isotonic contractions, but that muscles which shortened a great deal against a light load actually consumed less oxygen than muscles contracting isometrically. Whalen and Collins<sup>6</sup> confirmed the latter finding, but found no evidence of the Fenn effect, even with the muscle performing near maximal work. In an attempt to explain the difference between my results and those from heat measurement and chemical analysis, I considered the possibility that in my work the resting respiration provided a pool of 'extra' energy which was ordinarily converted directly to heat. If isotonic contractions used more of this surplus energy than isometric ones, evidence might not have been seen of it. When we found that the resting respiration could be suppressed without apparent detriment to the muscle<sup>7,8</sup> the possibility seemed less remote. It suggested that the Fenn effect might become obtrusive when larger muscles, or a lower  $pO_2$  or temperature, were used. Indeed, previous work had been performed with larger muscles than I had used, at lower temperatures (0°–17° C) and, often, lower  $pO_2$  (ref. 6). It is suggestive that Fischer "could find no evidence of the Fenn effect when the temperature was more than 17° C". The present communication is a report of the attempt to suppress the resting respiration by low  $pO_2$  and a somewhat lower temperature than I used previously, with the expectation that the extra energy for work would become apparent.

Except as mentioned, the experimental conditions and the muscles used were similar to those in my previous report with Collins<sup>6</sup>. Oxygen consumption was measured volumetrically in chambers designed to accommodate the frog sartorius muscle full-length rather than looped as previously<sup>6</sup>. Each of three chambers contained 9 ml. Ringer's bicarbonate solution with glucose as the substrate. The medium was agitated by a magnetic rotor in the chamber. The content of carbon dioxide in the gas phase (about 5 c.c.) was maintained near 2 per cent by using as the carbon dioxide 'absorber' a mixture of 70 parts of 3 M potassium bicarbonate and 30 parts of 3 M potassium carbonate plus carbonic anhydrase<sup>9,10</sup>. At the bath temperature of 22.4° C the pH was  $7.2 \pm 0.1$ . A mercury seal in the chamber top enabled the measurement of muscle tension or shortening to be made<sup>6,11</sup>.

The muscles (obtained from small *R. pipiens*) had a mean dry weight of 8.8 mg (cf. ref. 6). One of a pair of muscles was mounted at *in situ* length in one chamber, and its counterpart in another. The third chamber served as a control. On alternate days the chambers were gassed with either 98 per cent oxygen–2 per cent carbon dioxide, or 25 per cent oxygen–73 per cent nitrogen–2 per cent carbon dioxide. After gassing for 15 min, 45 min were allowed for a state of equilibrium to be reached, then readings were taken at least every 30 min, for a total of 6 h. After the oxygen consumption stabilized, both muscles were stimulated at a rate of 150/min for 3 min. One muscle was allowed to shorten and lift a near optimum load (5 g), the other merely exerted tension on a strain gauge. At the end of the experiment the muscles were removed, the pH of the medium determined;

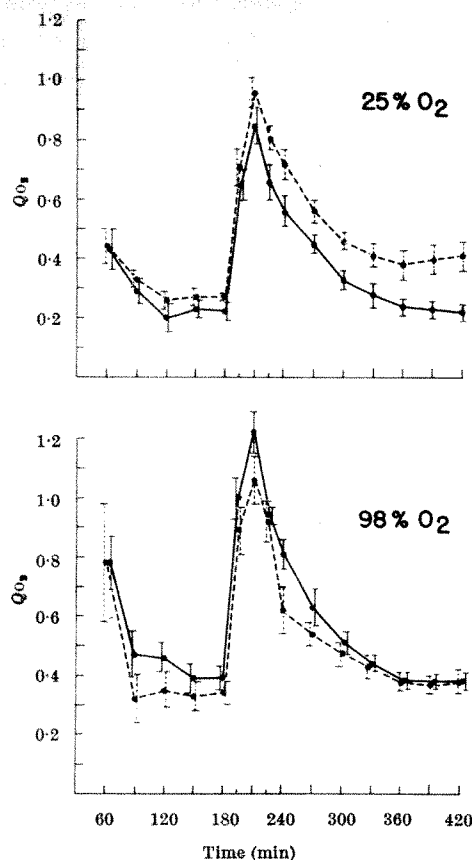

Fig. 1. Mean  $Q_{O_2}$  and S.E. (vertical bars) of 8 pairs of muscles exposed to 25 per cent oxygen and 8 pairs to 98 per cent oxygen. (The S.E. includes interindividual variation.) Stimulation at 150/min for 3 min began 180 min after placing the muscles in the chamber. —, Tension; ---, work

and, usually, aliquots taken for lactic acid analysis. The muscles were dried overnight at 100° C and weighed. Oxygen consumption is expressed as ' $Q_{O_2}$ ', that is,  $\mu V$  (s.t.p./mg (dry wt.)/h).

The resting  $Q_{O_2}$  was at first high, especially in 98 per cent oxygen, and dropped in about an hour to a steady level (Fig. 1). As expected from our previous investigations, the  $Q_{O_2}$  in 25 per cent was significantly lower than the value in 98 per cent oxygen<sup>6</sup>. We also confirmed our previous results<sup>6</sup> that, in 98 per cent oxygen, muscle which performed substantial amounts of mechanical work consumed no more oxygen than muscles which did essentially none (Fig. 1). On the other hand, muscles which contracted isotonically in 25 per cent oxygen consumed significantly more oxygen than their isometrically contracting mates. The work performed or tension developed by the muscles was independent of the  $pO_2$ , as was lactic acid liberation, in confirmation of previous results. There was a tendency for the lactic acid liberation to be higher in muscles which did work. However, no experiments would have to be performed to establish any significance.

Since the  $Q_{O_2}$  of the muscle which contracted isotonically in 25 per cent oxygen did not return to the control level, it is impossible to quantitate the work done with the extra oxygen consumed. Indeed, if the hypothesis is correct, that resting respiration represents a relative large pool of available energy, no correlation would be meaningful unless one knew the extent to which isotonic contractions dipped into the pool. That others were able to find evidence of the Fenn effect could be due to the fact that the investigators used larger muscles, low  $pO_2$ , or a low experimental temperature<sup>1-3</sup>, all of which would be expected to reduce the pool of 'resting' energy.

It seems probable that the same explanation underlies the failure to find evidence for the Fenn effect in isolated rat muscle<sup>11</sup>. In this connexion, Lentini<sup>12</sup> found that isolated rat trabeculae the oxygen consumption was the same whether the strips were contracting or quiescent. Likewise, in nerve, apparently normal conduction can go on for hours without apparent additional energy cost<sup>13</sup>. These functions may simply use 'pool' energy.

The concept of a pool of 'excess' energy would tend to found interpretation of investigations which attempt to relate consumption of oxygen to other cell functions, such as the active transport of sodium<sup>14,15</sup>. Obviously, the efficiency of the transport system, calculated on the basis of consumption of oxygen, would vary considerably, depending on the experimental conditions. It seems pertinent that the effect of metabolic inhibitors on ion transport depends very much on the temperature<sup>16</sup>. In investigations of energetics it might be necessary to investigate the process, in nitrogen<sup>17</sup> or *in vivo*, where the energy may be supplied according to the demand and less energy-utilization of oxygen is likely. However, even *in vivo*, Fales, Heisey and Zierler<sup>18</sup> were unable to find evidence for the Fenn effect in dog skeletal muscle. I thank Mrs. W. Bosch for her help in this work, which is supported (in part) by U.S. Public Health Service Grant H5390.

## PHARMACOLOGY

### Influence of Amino-oxidase Inhibitors on the Psychomotor Depression produced by an Intraperitoneal Injection of Adrenaline in Mice

In earlier papers<sup>1,2</sup> the psychomotor depression produced by an intraperitoneal injection of catecholamines in mice was described. We found that the depression produced by adrenaline did not depend on peripheral autonomic phenomena and was not influenced by the inorganic blocking agent phentolamine ('Regitin'); it is, however, inhibited by methylamphetamine<sup>3</sup>.

It seemed to us worth while to examine the effect of amino-oxidase inhibiting substances on the psychomotor depression produced by adrenaline. We used two inhibitors having different mechanisms of action, that is, iproniazid, a hydrazine derivative which acts by chemical inactivation of the amino-oxidase, and tranyleypromine, an amphetamine derivative, antagonizing it competitively. The method used in these experiments has been described in our preceding papers<sup>1,2</sup>. Iproniazid was injected in doses of 100 and 200 mg/kg. The dose of

100 mg/kg was injected 2 and 18 h before injecting adrenaline. The dose of 200 mg/kg was injected 18 h before the administration of adrenaline. All injections were applied intraperitoneally. Tranyleypromine was injected in doses of 1, 2, 5 and 10 mg/kg, always 2 h before the administration of adrenaline. The psychomotor activity of the animals was registered 15 min after the injection of adrenaline for 10 min in an actophotometer.

The results are shown in Table 1. Each group consisted of 7-21 animals.

Table 1

Distilled water	Adrenaline 1 mg	Adrenaline 2 mg
51 ± 8	17 ± 4	5 ± 1
Iproniazid 100 mg 2 h before	46 ± 15	10 ± 4
Iproniazid 100 mg 18 h before	40 ± 11	13 ± 3
Iproniazid 200 mg 18 h before	59 ± 8	11 ± 3
Tranyleypromine 1 mg	17 ± 4	7 ± 2
Tranyleypromine 2 mg	67 ± 16	12 ± 5
Tranyleypromine 5 mg	78 ± 15	29 ± 19
Tranyleypromine 10 mg	100 ± 15	81 ± 17

The values in Table 1 correspond to the actophotometer readings  $\pm$  S.D.M. These values show that iproniazid in doses of 100 and 200 mg does not effectively modify the psychomotor activity.

The same substance given 2 or 18 h before an injection of adrenaline has no significant effect on the psychomotor depression caused by the last substance.

The situation with tranyleypromine is different. This substance in doses of 2 and 10 mg/kg enhances somewhat the psychomotor activity and in doses between 1 and 5 mg/kg eliminates completely the psychomotor-depressing action of 1 mg/kg adrenaline, but not that of 2 mg/kg of this substance. 10 mg/kg of tranyleypromine not only inhibited the depressing action of adrenaline (even that of the dose of 2 mg/kg) but also produced an enhanced psychomotor activity.

We suppose that tranyleypromine acts in these experiments not by inhibition of the amino-oxidase, but as an amphetamine derivative showing an effect similar to that of this drug. Our opinion is based on the fact that iproniazid manifested no clear antagonism to the psychomotor depressing action of adrenaline.

### Formation of Two Spots caused by 'Secondary Adsorption' in Paper Chromatography of Primycin

We have shown<sup>1</sup> that primycin, an agent of strong antituberculous effect belonging to the group of guanidino antibiotics, is not identical with any of the known antibiotics. On the basis of its colour reactions and of its infra-red and ultra-violet spectra<sup>2</sup>, the molecule of primycin ( $C_{19}H_{37}O_7N_5$ ) contains an N—H group and several O—H groups; it is inclined to molecular associations and it discloses adsorptive properties. On subjecting primycin to paper chromatography, the formation of a second spot was observed. This was due to the so-called 'secondary adsorption' of an accompanying substance present in minute amounts.

Fig. 1

Fig. 2. Changes in  $R_F$  values and migration periods ( $t$ ) in hours, plotted against acetone concentration. —, Spot 'A'; ---, Spot 'B'.

The anomalous phenomena of 'tail formation' and of formation of two or more spots in the paper chromatography of a single substance have already been dealt with in the case of sugars<sup>3</sup> and antibiotics<sup>4</sup>. Though the phenomenon has been observed and described by several authors, its interpretation has been based solely on assumptions. However, it was proved by Soholsky *et al.*<sup>5</sup> that in the case of novobiocin, depending on the nature of the dropping solvent, the solvate or hydrate of novobiocin was actually adsorbed by cellulose as a separate spot. Primycin, dissolved in any of its solvents and allowed to dry on paper, retained its property of forming two spots. Thus, in the mechanism of paper chromatography, in addition to partition effects, other competitive influences such as 'secondary adsorption' may also emerge.

**Experimental technique.** The paper strip technique generally applied in the case of antibiotics was followed, while the circular method was used for the partition of larger quantities. Chromatography was carried out by ascending development at room temperature, using  $10 \times 180$  or  $10 \times 290$  mm strips of filter paper (Schleicher and Schüll '2043/b'). The amount of primycin dissolved in butanol/ethanol/water (1 : 1 : 2 v/v) (BEW)<sup>2</sup> and dried on

paper, indicated by 'autobiography' against *B. subtilis* ranged from 0.5 to 10  $\mu\text{g}$ , while on detection by the N-bromo-succinimide modification of the Sakaguchi colour test<sup>2</sup> it varied from 50 to 200  $\mu\text{g}$ . The  $R_F$  values were established from the mean values of spots which were allowed to run parallel.

The adsorption mechanism of the formation of two spots in the case of primycin was statistically supported by the data of chromatograms<sup>6</sup> investigated by 'autobiography' in 40 different solvent systems, with three exceptions (7.5 per cent), only a single spot was observed. A 45 per cent mixture of acetone and water proved to be the most suitable for the investigation of the causes which lead to the formation of two spots (Fig. 3, strips 1-2). The two spots also appeared on paper previously subjected to exhaustive extraction by benzene and methanol (Soxhlet) proving that the phenomenon is not essentially affected by the contaminations of filter paper. As to the effect of the quantities of substance transferred on the paper, it was found that a single zone appeared with 1  $\mu\text{g}$  of primycin whereas two spots formed with 2, 4, 6  $\mu\text{g}$  or more. In contrast, on running amounts of 50-200  $\mu\text{g}$  of primycin for example, in the system *n*-BuOH-Ac.ac.-H<sub>2</sub>O (40 : 10 : 50), only one spot was observed ( $R_F$ : 0.56-0.61). To determine how these two spots of primycin could have been formed, the antibiotic was allowed to run to various frontal distances in the critical acetone-water solvent mixture. The antibiotic content of the upper 'B' spot (of higher  $R_F$  value) proved to increase gradually with the progress of the solvent while that of the lower 'A' spot proportionately decreased. Consequently, changes took place in the antibiotic content of the spots during migration. Thus, the presence of another active substance or of an eventual isomer of primycin cannot be assumed. When the position of the spots was simultaneously established on control strips, the chromatogram was correspondingly divided and run again in the same solvent, all the 'A' and 'B' spots appeared at an identical  $R_F$  value (0.85), indicating that they originate from one single type of primycin. However, the problem of the 'two active agents' of primycin still remained doubtful in the case of two-dimensional chromatography.

Fig. 3

In applying paper strips and *n*-butanol saturated with ter, chromatograms with only one spot were always served. When larger amounts (200  $\mu$ g) of primycin re subjected to partition by the circular method, and Sakaguchi reaction<sup>2</sup> was used for indication, spots and 'B' formed with this solvent (Fig. 1). On cutting these spots and eluting them with methanol, the plates were allowed to run separately with *n*-butanol on the paper strips. Spot 'B' remained unchanged while 'A' formed two. Consequently, the accompanying contamination formed a separate system on the paper per + contamination + primycin), resulting in the titting of primycin. Later, the effect of the solvent tern acetone-water on the fractionation of primycin s investigated by 'autobiography'. Two spots formed h acetone concentrations from 35 to 55 per cent; ler identical conditions only one spot appeared h acetone concentrations of 60-90 per cent (Fig. 2). Fig. 2 the changes in  $R_F$  values and the migration iods of the solvent mixtures were plotted against concentrations of acetone (in steps of 5 per cent). It be seen that in solvents which migrate slowly (up 50 per cent acetone) two spots of primycin formed, ile in solvents which migrate more quickly (50-90 cent acetone) only one spot appeared, presumably to the absence of the accompanying substance. If conclusion drawn from the experimental data is rect, no two spots may reappear when the single spot primycin obtained by running in 70 per cent acetone g. 3, strips 3-4) is again chromatographed in 45 per acetone (strips 5-8). In fact, on carrying out this ond chromatography in paper strips of double length, phenomenon of 'secondary adsorption' due to the ged contaminant was no longer observed. n further experiments, the purity of primycin was ified not only by paper chromatography but also by titution column chromatography, and was supported exact data obtained by counter-current extraction aig) partition and fractionated crystallization. In all cases only one active substance was detected which closed constant analytical values.

## HAEMATOLOGY

### Specific Technique for the Isolation of Human $\alpha_2$ -Macroglobulin

ORMAL human serum contains two kinds of macrobulin, the  $\gamma_1$ M (or  $\beta_2$ M)-group and  $\alpha_2$ -macroglobulin; latter was first isolated and described by Schultze l co-workers<sup>1</sup>. The macroglobulin isolated by Brown d. from Cohn's Fraction III<sup>2</sup> seems to be the same tein<sup>3</sup>. Although  $\alpha_2$ -macroglobulin corresponds to ut 3 per cent of total serum protein, its biological ifficance is still unknown. This may be a sufficient lanation for the rather scarce literature concerning it. wever, it seems to us that the main reason might be the iculty of obtaining this protein in a pure state and in ficient quantity. This involves a complete fractionation

scheme<sup>1,2</sup>, or the use of small-scale techniques involving ultracentrifugation or preparative electrophoresis<sup>3-5</sup>. A specific and simple isolation technique is still lacking.

The technique we propose is based on the precipitation of a protein fraction containing the  $\alpha_2$ -macroglobulin by 'Rivanol' (diamino-ethoxyacridin-lactate) adsorption of the contaminating plasminogen on bentonite and adsorption of impurities on DEAE-cellulose. Table 1 gives the details of this fractionation scheme.

Table 1. ISOLATION TECHNIQUE FOR  $\alpha_2$ -MACROGLOBULIN

Plasma	Proteins 5 per cent; pH 8.6
Supernatant	1 vol. + 1.8 vol. 'Rivanol' 0.5 per cent pH 6.4
Precipitate	1 vol. + 0.44 vol. 'Rivanol' 0.5 per cent Supernatant discarded Dissolution (1/5 initial volume) 3 per cent NaCl Insoluble material is discarded Dialysis against water (2 h) Re-precipitation with 'Rivanol' (0.38 vol.)
Precipitate	Supernatant discarded Washing with distilled water Dissolution (1/10 initial volume) 3 per cent NaCl; 2-h dialysis against water Dilution to 1.5 per cent protein concentration; $\Delta t = -0.14^\circ$ ; pH 8.6 Absorption of plasminogen by bentonite (3 per cent) for 30 min
Supernatant	Centrifugation pH 5 (with dilute acetic acid) Adsorption of contaminating proteins on DEAE equilibrated at pH 5 against acetate buffer 0.015 M (60 g pressed, humid cellulose for 1 g of protein)
Pure $\alpha_2$ -macroglobulin	remains in solution

The first precipitate, obtained by addition of a 0.5 per cent 'Rivanol' solution at pH 8.4, is discarded, and the second precipitate, obtained at pH 6.4, contains the  $\alpha_2$ -macroglobulin. This precipitate is dissociated by 3 per cent NaCl and the protein solution is separated by centrifugation from the insoluble material (mainly 'Rivanol'), and after a short dialysis against distilled water the second precipitation step is repeated. The resulting precipitate is washed with cold water, dissociated with 3 per cent NaCl as before, and dialysed.

At that stage starch-gel electrophoresis showed that  $\alpha_2$ -macroglobulin was mainly contaminated by some haptoglobin and other  $\alpha_2$ -globulins; immunoelectrophoresis revealed, in addition to these proteins, the presence of  $\beta_2$ A-globulin.

Some years ago we isolated haptoglobin by chromatography on DEAE-cellulose at pH 5 in the presence of 0.03 M acetate buffer<sup>6</sup>. A small modification of the original technique allows adsorption of haptoglobin as well as the  $\alpha_1$ -globulins and  $\beta_2$ A-globulin, whereas  $\alpha_2$ -macroglobulin is not adsorbed. Unfortunately, routine testing for proteolytic activity showed that the  $\alpha_2$ -macroglobulin prepared by this method contains considerable amounts of plasminogen. There seems to be a real molecular affinity between the pro-enzyme and  $\alpha_2$ -macroglobulin, and plasminogen proved to be a very tenacious contaminant. The best result has been obtained by adsorption of plasminogen on bentonite, the adsorption step being carried out between precipitation by 'Rivanol' and the adsorption of impurities on DEAE-cellulose.

Several preparations submitted to analytical ultracentrifugation (the analytical ultracentrifugation data were provided by the Station Centrale d'Ultracentrifuga-

Fig. 1. Immuno-electrophoresis: 1.4 per cent solution of  $\alpha_2$ -macroglobulin. An anti-human serum from the Netherlands Red Cross Blood Transfusion Centre

tion du C.N.R.S.) revealed 91–94 per cent of homogenous 19 S component. By a second chromatography on DEAE under the same conditions we obtained a preparation containing 97 per cent heavy component. The residual 2 per cent of the preparation corresponds to a 12 S component which might eventually be found to correspond to a degradation product of  $\alpha_2$ -macroglobulin. Indeed, immunoelectrophoresis of a 1.4 per cent solution of  $\alpha_2$ -macroglobulin revealed a single precipitation line when tested with whole anti-human serum (Fig. 1). A similar observation has been made by Filitti-Wurmser and Hartmann for  $\alpha_2$ -macroglobulin obtained by ultracentrifugation and dialysis.

Thus, the proposed technique provides a means of obtaining pure  $\alpha_2$ -macroglobulin, the procedure needing neither preparative ultracentrifugation nor preparative electrophoresis. The total yield is about 50 per cent calculated on the basis of a theoretical concentration of 2.1 g/l. of plasma.

## HISTOLOGY

### Haarscheiben in the Skin of Sheep

ON the skin surface of many mammals, including man, there are mounds of epidermis, called 'haarscheiben', which are characterized by several layers of epithelial cells overlying an area of connective tissue that is highly innervated and vascularized<sup>1,2</sup>. The haarscheibe is an integrated part of the highly specialized tylotrich follicle<sup>3,4</sup>. Although the formation and morphology of sheep hair follicles are well known<sup>5</sup>, haarscheiben have not been found. The present communication describes haarscheiben in sheep skin and shows that they are associated with a particular type of hair follicle.

Skin samples were removed from the dorsum and venter of three 8-month-old  $F_1$  hybrid sheep (Cheviot  $\times$  Suffolk). Each skin specimen was clipped, depilated with barium sulphide, and examined under a low-power microscope for the presence of haarscheiben. Circular haarscheiben were clearly visible on the skin surface (Fig. 1). Associated with each of these structures was a hair, which generally emerged slightly caudal to the centre of the haarscheibe (Fig. 1). The mean diameter of ventral haarscheiben was larger than that of those found on the dorsum (Table 1). Similar results were observed in the mouse<sup>6</sup>. Many of the haarscheiben on the dorsum of the sheep contained clumps of pigment granules, but this was not seen on other parts of the skin surface.

Table 1. DIAMETER OF SHEEP HAARSCHIEBEN

Skin area	Haarscheiben		S.E.	t*	P
	No. observed	Mean diam. (mm)			
Caudal dorsum	20	0.263	$\pm 0.007$	8.48	< 0.001
Venter	30	0.380	$\pm 0.010$		

\* Based on Fisher's small-sample *t* test.

About forty haarscheiben with some surrounding tissue were excised from the skin specimens. Some tissues were impregnated with gold chloride<sup>7</sup>. Others were placed in

Fig. 1. Haarscheibe on the ventral skin surface of the sheep. The orifice of the hair canal is marked with an arrow. Another hair shaft which lacks a haarscheibe is shown on the right ( $\times 475$ ).

Fig. 2. Longitudinal section through a haarscheibe, showing the firmer connective tissue under the thickened epidermis. Section stained with alum haematoxylin and eosin ( $\times 134$ ).

either Bouin's or Lavdowsky's fixatives. All tissues were embedded in paraffin, sectioned serially at  $7\mu$ , and stained with alum haematoxylin and with either eosin or van Gieson's picric-acid fuchsin stain.

The haarscheibe of the sheep is composed of several layers of epithelial cells, the number of cell layers decreasing abruptly on both sides of the haarscheibe (Fig. 2). The lower cell layers of epidermis are morphologically distinct. The basal layer consists of highly specialized cells containing large amounts of cytoplasm (Fig. 3). The next layer contains elongated epithelial cells with spindle-like nuclei, many of which stain deeply with haematoxylin. Underlying the epidermis is a specialized region of dermis composed of fine connective tissue fibres. Throughout this region are many capillaries and fine nerves (Fig. 2).

In addition to the haarscheiben, tylotrich follicles characterized by a specialized area of tissue just below the level of the sebaceous glands. This sensory area,

Fig. 3. A tangential section through a haarscheibe showing the specialized cells at the base of the epidermis, one of which is marked with an arrow. Section stained with alum haematoxylin and eosin ( $\times 1,105$ )

annular complex, consists of a prominent network of nerve fibres surrounded by an annular arrangement of highly vascularized connective tissue<sup>3,4</sup>. The annular complex is observed most readily in the resting phase of the hair growth cycle; during the growth phase it is depressed and obscured<sup>4</sup>. All the sheep follicles examined were growing, and the annular complexes were not observed. Nevertheless, sheep haarscheiben are associated with distinct hair follicles.

Sheep hair follicles are classified into primary follicles, which possess sweat glands and arrector pili muscles, and secondary follicles, which lack these accessory structures<sup>5,6</sup>. Each follicle associated with a sheep haarscheibe possesses a sweat gland and arrector pili muscle, indicating that tylotrich follicles are in the primary follicle group. Primary follicles are divided further into central primary follicles, the first follicles to appear in the foetus, and lateral primary follicles, which begin to form a few days later<sup>5</sup>. Which of the two sheep primary follicle types possesses haarscheiben is not known, but by comparison with mouse tylotrich follicles, which are the first to appear in the foetus<sup>6</sup>, it is suggested that the central primary follicles have the haarscheiben.

### Survival of Chromaffin Cells in Organ Culture of the Adrenal Medulla

AUTOGRAFTS of the adrenal medulla are known to survive for weeks in the anterior chamber of the eye, retaining their cytological properties and catecholamine content<sup>1,2</sup>. On the other hand, few attempts have been

Fig. 1. Formaldehyde-induced fluorescence in a piece of the adrenal of a new-born rat after cultivation for 20 days. Medullary cells exhibit an intense cytoplasmic fluorescence, while cortical cells are essentially non-fluorescent ( $\times 50$ )

made to cultivate adrenal medullary tissue *in vitro*<sup>3,4</sup>. Experiments carried out in our laboratory led to the development of a simple technique by which it is possible to keep adrenal medullary cells alive in culture for several weeks.

Small pieces of adrenal medulla of adult Sprague-Dawley albino rats, and pieces of whole adrenals of new-born rats, were dissected under sterile conditions. The fragments were cultivated in a plastic Petri dish on a chicken plasma and embryo extract coagulum. The culture medium consisted of a mixture of 2 volumes of Hanks's balanced salt solution with 5 mg/ml. of lactalbumin hydrolysate, one volume of amino-acid-Parker and one volume of Seitz-filtered calf serum inactivated for 30 min at 56° C. The Petri dishes were incubated in a

Fig. 2. Electron micrograph showing a medullary cell from a 39-day culture of the adrenal of a new-born rat. Note the small electron-dense vesicles typical of the adrenal medulla, the mitochondria above, and the Golgi apparatus below the nucleus. Palade's fixative, embedding in Epon ( $\times 4,000$ )

humidified air atmosphere continuously supplied with a flow of  $\text{CO}_2$  sufficient to keep the pH at 7.4 in the culture medium.

After varying periods of cultivation, pieces were removed from the culture and they were examined histochemically, using the chromaffin reaction or formaldehyde vapour-induced fluorescence for the demonstration of catecholamines<sup>5</sup>, or by electron microscopy after fixation in Palade's solution and embedding in 'Epon'. Pieces of fresh adrenal glands were similarly treated and served as controls.

The intensity of the chromaffin reaction weakened in the medullary cells during the first 1-3 days of culture. Thereafter the reaction intensity was again similar in the surviving cells and in fresh controls. After 2-3 weeks' culture, the chromaffin reaction of the medullary cells of new-born rats was sometimes even more intense than normal. Formaldehyde-induced fluorescence (Fig. 1) also indicated at least normal catecholamine content in pieces cultured for up to 60 days. Although many cells thus clearly retained their ability to store and possibly to synthesize catecholamines, other cells obviously died during cultivation, especially in cultures of pieces taken from adult animals; pieces from new-born rats survived better.

The ultrastructure of the cultured cells (Fig. 2) corresponded to that of the controls. Droplets containing catecholamine, and surrounded by a membrane, were of typical structure, as were other cytoplasmic organelles, such as mitochondria.

Cultures of this kind may facilitate the investigation of, for example, direct effects of drugs on adrenal medullary cells.

## HISTOCHEMISTRY

### Staining of Bacteriophage Nucleic Acids with Acridine Orange

THE use of the fluorescent stain acridine orange for the quick identification of viral nucleic acids has been described by Mayor and Hill<sup>1</sup>. In this valuable technique colour differences permit differentiation between double-stranded deoxyribonucleic acid (DNA), on one hand (fluoresces green), and ribonucleic acid (RNA) and single-stranded DNA on the other (fluoresces red). The latter nucleic acids can be separated by their respective sensitivities to RNase and DNase. While the procedure of Mayor and Hill is simple compared with the techniques of biochemical analysis, it involves numerous treatments and the use of fluorescence microscopy. Furthermore, acridine orange staining is particularly sensitive to pH levels, and, because of this, some difficulty may be experienced in obtaining the correct colours. In addition, the procedure does not differentiate between single-stranded DNA and RNA, using the stain alone. This communication describes some improvements and modifications with these points in mind. Direct viewing under ultra-violet light is substituted for the fluorescence microscope, the pre-staining treatment is simplified, and possible unreliability due to pH sensitivity is eliminated.

The method is as follows. The reagents required are Carnoy's fixative, 0.1 M citric acid, 0.15 M  $\text{Na}_2\text{HPO}_4$ , 1

per cent acridine orange in water and buffered saline ( $\text{Na}_2\text{HPO}_4$ , 1.27 g/l.;  $\text{KH}_2\text{PO}_4$ , 0.41 g/l.; NaCl, 7.36 g/l. pH 7.2).

Droplets of a virus suspension ( $10^{10}$ - $10^{12}$  particles/ml in buffered saline) are dried down on to microscope slide. The slides are transferred to Carnoy's fixative for 5 min then rinsed in absolute alcohol and dried in a stream of warm air. The material is stained with acridine orange for 5 min in the following modified McIlvaine's buffer: 6 ml. 0.1 M citric acid; 4 ml. 0.15 M  $\text{Na}_2\text{HPO}_4$ ; 0.1 ml. 1 per cent acridine orange; pH 3.8. The slides are rinsed in 6 ml. 0.1 M citric acid + 4 ml. 0.15 M  $\text{Na}_2\text{HPO}_4$ , and transferred to 0.15 M  $\text{Na}_2\text{HPO}_4$  for 15 min. Excess liquid is shaken off and the slides are examined under an ultraviolet lamp (wave-length 2570 Å), the colour of the smears being noted. If the smears are red, the slides are placed in 0.1 M citric acid and examined in ultra-violet light at intervals of 1, 2 and 3 min, the colour change being noted.

The results obtained with various bacteriophages, etc are summarized in Table 1.

Table 1

Specimen	Nucleic acid	$\text{Na}_2\text{HPO}_4$	Citric acid
Phage T4	2-stranded DNA	Yellow-green	—
Phage $\phi$ L <sup>2</sup>	Unknown	Yellow-green	—
Mouse liver DNA	2-stranded DNA	Yellow-green	—
Mouse liver DNA (denatured)	1-stranded DNA	Flame-red	Stays red but fades noticeably
Phage $\phi$ R <sup>3</sup>	1-stranded DNA	Flame-red	Goes pale green then fades
Phage ZJ/2 <sup>4</sup>	1-stranded DNA	Flame-red	Stays red but fades noticeably
Phage $\phi$ 12 <sup>*</sup>	Unknown	Flame-red	Fades completely
Phage ZIK/1 <sup>4</sup>	RNA	Flame-red	Stays red, does not fade
Phage ZJ/1 <sup>4</sup>	RNA	Flame-red	Stays red, does not fade

\*A filamentous form similar to ZJ/2.

It can be seen that viruses with double-stranded DNA are quickly distinguished from others by their colour after treatment with phosphate. The green is bright and quite unmistakable, though there is sometimes a trace of red in the centre of the smear if the phage concentration is high. If green is obtained there is obviously no need for treatment with citric acid. In fact, this causes the colour to change to red and fade. Both single-stranded DNA and RNA phages produce flame-red colour after phosphate treatment. The colour is almost crimson and there is no trace of green. The citric acid treatment helps to distinguish these two types of nucleic acid. The criterion is that RNA phages do not fade over the 3-min period whereas the single-stranded DNA phages fade noticeably and may be accompanied by a change to green. While this test is to a certain extent subjective, it can be used to confirm other indications as to the type of nucleic acid. For example, a phage which is subject to plaque inhibition by RNase<sup>4</sup>, the red fluorescence of which does not fade in citric acid, undoubtedly contains RNA. If additional confirmation is required, however, Carnoy fixed slides may be treated with RNase or DNase<sup>1</sup>. Subsequent staining will produce no fluorescence with the appropriate nucleic acid.

The procedure must be strictly followed for satisfactory results and virus preparations should be free from contaminating nucleic acids.

I thank Prof. M. M. Swann for his advice and Dr P. M. B. Walker for mouse liver DNA.

## IMMUNOLOGY

Prevention of Immunological Tolerance to *Shigella* Antigens in New-born Mice by Immune Spleen Cell Extracts

IMMUNOLOGICAL capability may be restored in tolerant animals by means of spleen or lymph node cell transplants from normal or immune donors<sup>1,2</sup>. In somewhat similar situations, establishment of tolerance to *Shigella dysenteriae* antigens<sup>3</sup> and to bovine serum albumin<sup>4</sup> has been prevented in neonatal mice by simultaneous administration of normal spleen or thymus cell suspensions obtained from either neonatal or adult donor mice. In the *Shigella* system, it was found that viable lymphoid cells were apparently necessary for interference with establishment of tolerance. Heat-killed normal lymphoid cells, and non-lymphoid tissue suspensions from liver, lung, kidney and brain, were not effective<sup>3</sup>. During the course of these investigations, it was found that transfer of spleen cell suspensions from adult donor mice previously immunized to *Shigella* antigens was more effective in blocking tolerance than transfer of cells from either neonatal or normal adults<sup>3</sup>.

It was not clear whether such interference was due exclusively to the transferred immune cells, or could be attributed to passive transfer of anti-*Shigella* antibody. In order to clarify this point, experiments were performed to test the ability of cell-free extracts from *Shigella* immune mice to prevent establishment of tolerance. For this purpose, spleen cell suspensions were obtained from groups of NIH adult mice which had been immunized 4–7 days previously with a single intramuscular injection of 0.1 ml. *Shigella* soluble antigen (20 µg N), derived by trypsin digestion from alcohol-killed *Shigella* organisms<sup>5</sup>. For preparation of 'immune' extracts, spleens were obtained only from mice exhibiting serum agglutinin titres of 1:1,024 or higher. The spleens were washed in cold, sterile Hanks's solution, trimmed free of excess fat, and 'teased' into Hanks's solution, pH 7.2, containing 20 per cent sterile calf's serum. A 10-ml. suspension containing 5 to 10 × 10<sup>7</sup> viable nucleated cells per ml. was subjected to alternate freezing and thawing for 10 min. The cell debris was removed by centrifugation at 6,000g for 10 min. The clarified supernatant was filtered through 'Millipore' membranes (0.45 µ), dialysed against saline for 4 h in the cold, and lyophilized. The extracts were stored at -20° C until used. Control extracts were prepared from (a) immune spleen cell suspensions which had been heated for 30 min at 56° C, and (b) spleen cell suspensions prepared from normal, non-immune adult NIH mice.

All spleen cell extracts were rich in mouse γ-globulin as revealed by gel diffusion and immunoelectrophoretic analysis using rabbit anti-mouse whole serum of high titre. The immune extracts had anti-*Shigella* agglutinin titres of 1:10,240 or higher as a solution of 1 mg extract or ml. saline. The heated extracts had titres of 1:640–1:2,560, while non-immune extracts had titres of 1:128 or less. These extracts were tested for their ability to interfere with the establishment of tolerance in new-born mice injected with *Shigella* antigen. Mice were injected intraperitoneally (i.p.) within 12 h of birth with 0.1 ml. *Shigella* soluble antigens (20 µg N). Control mice from the same litters were injected with saline. Groups of new-born mice receiving either *Shigella* or saline were then inoculated i.p. with the concentrated extracts obtained from (a) *Shigella*-immune spleen cells, (b) heated *Shigella*-immune spleen cells, (c) normal spleen cells or (d) saline only. Each mouse received 0.1 ml. extract containing 0.8–0.5 mg N. Five to six weeks thereafter, all surviving mice were challenged by means of an intramuscular injection of *Shigella* antigen. Blood samples were obtained by retro-orbital puncture before challenge, and at close intervals hereafter for 2–3 weeks. The samples were tested for

anti-*Shigella* agglutinins by standard test-tube agglutination procedure or in micro plastic cups using calibrated wire loops and 0.025 ml. volumes of serum dilutions and killed *Shigella* organisms.

Table 1 presents results obtained in a typical series of experiments. New-born mice injected with *Shigella* antigen only at birth were markedly deficient in ability to respond to challenge immunization with *Shigella* at five to eight weeks of age (group A). Similarly treated mice which received spleen cell extracts from *Shigella*-immune donor mice were competent to form anti-*Shigella* agglutinins following challenge injection (group C). Such extract-treated mice receiving *Shigella* antigen at birth responded nearly as well as control mice (group B) which received no inoculations at birth. Administration of extract from normal mice had no effect on establishment of tolerance (group F). However, extracts from heat-treated spleens still retained some ability to prevent establishment of tolerance (group E). Transfer of extracts to mice not receiving an injection of *Shigella* at birth (to induce tolerance) had no detectable effect on agglutinin formation after challenge injection (group D).

Table 1. EFFECT OF TRANSFER OF VARIOUS CELL-FREE EXTRACTS FROM DONOR IMMUNE SPLEEN CELLS ON ESTABLISHMENT OF TOLERANCE TO *Shigella* IN NEW-BORN RECIPIENT MICE

Group	No. of mice	<i>Shigella</i> injection at birth*	Extract transferred at birth†	Agglutinin response after challenge injection No. positive‡ No. injected	Mean peak titres

B	14	—	Saline	11/12	1:417
C	18	+	Immune spleen	11/14	1:372
D	11	—	Immune spleen	8/9	1:402
E	18	+	Heated immune spleen	6/15	1:220
F	15	+	Normal spleen	1/11	1:29

\* 0.1 ml. *Shigella* soluble antigen (20 µg N) injected intraperitoneally within 12 h of birth.

† 0.1 ml. of saline or spleen cell extract (0.8 to 1.5 mg N) injected intraperitoneally in recipient mice within 12 h of birth.

‡ No. of mice with agglutinin titre of 1:128 or higher after challenge injection with *Shigella* antigen at 5–6 weeks of age.

Graded doses of immune spleen cell extracts were administered i.p. to various groups of new-born mice. Injection of 5, 2, 1, 0.5 and 0.1 mg N extract was found to be effective in preventing establishment of tolerance. Administration of lower dosages was ineffective. Absorption of concentrated extract with an equal volume of packed, alcohol-killed, *Shigella* micro-organisms for 30 min at 37° C, followed by high-speed centrifugation to remove the organisms, removed all activity capable of blocking tolerance. Such absorption also removed detectable anti-*Shigella* agglutinins from the extract. Treatment of extract with sheep red blood cells or packed *Salmonella typhosa* antigen had no effect.

The results presented here indicate that immunological tolerance induced in new-born mice by inoculation of a large dose of *Shigella* antigen may be prevented by a simultaneous inoculation of cell-free spleen extracts prepared from *Shigella*-immune adult donor mice. Such extracts contain relatively high levels of *Shigella* agglutinins. Absorption of agglutinins by incubation with *Shigella* vaccine eliminates the biological effectiveness of the extract. Non-immune extracts were not effective in preventing unresponsiveness. Other experiments in progress on the prevention of tolerance have suggested that mouse or rabbit anti-*Shigella* immune serum of high titre may also block tolerance. These findings suggest that tolerance to a non-living antigen such as *Shigella* soluble antigens may be prevented in new-born mice not only by lymphoid cell transplants, but also by specific antibody. The mechanism of such inhibition is not clear. Immune spleen cell extracts may contain an active antibody-forming mechanism (nucleoprotein-RNA-coding complexes) which actively induces agglutinin formation in new-born mice<sup>6</sup>. On the other hand, passively trans-

ferred extracts may contain antibody which inhibits postulated antigen-antibody complexes capable of blocking the induction of immunity in otherwise competent cells<sup>7</sup>.

### Immune Globulins in Human Viral Infections

EXTENSIVE investigations in animals, including man<sup>1-3</sup>, have shown that the first immune globulins which appear after a primary antigenic stimulus are of high molecular weight and can be readily inactivated by sulphydryl-reducing compounds such as 2-mercaptoethanol (2-ME). In most systems these antibodies, which will be referred to as 19S, are replaced within a few weeks by 7S  $\gamma_2$ -globulins which resist reduction. The 19S antibodies can be demonstrated in early post-immunization sera by sedimentation characteristics or more easily by titration of antibody activity before and after treatment with 2-ME. In late sera or following a secondary stimulus, 19S globulins make up no more than a small portion of total antibody so that 2-ME treatment does not result in over-all titre reduction.

It seemed that the relative amounts of 19S and 7S antibody might provide a valuable index for recognizing recent viral infections in humans and differentiating between primary and secondary immunological experiences. This has been tested and confirmed following measles, mumps and Coxsackie virus infections. Those vaccinated against measles were also examined to provide sera collected at accurately known intervals after infection.

Sera collected at various times after measles were fractionated by ultracentrifugation on sucrose gradients. Fractions were titrated for antibody content by the haemagglutination-inhibition (HI) method of Rosen<sup>4</sup>.

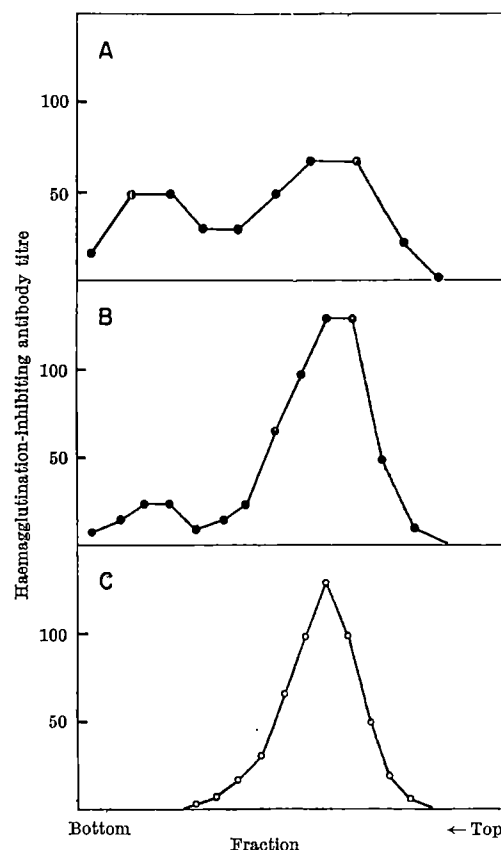

Fig. 1. Sedimentation analyses of measles antibodies in sera collected at various times after measles. A, 4 days after rash; B, same patient as in A, 19 days after rash; C, 1 year after measles. Each serum was layered on a five-step gradient ranging from 12.5 to 37 per cent w/v sucrose and centrifuged at 35,000 r.p.m. for 16.5 h in a Spinco SW-39 rotor. Fractions were collected through a hole pierced in the bottom of the tube.

Two peaks of antibody activity were found in sera following recent infections. The lower peak, shown on the left in Fig. 1, corresponded in position with heterophile antibody centrifuged under the same conditions as previously characterized as 19S globulin<sup>5</sup>. Acute phase sera (A, Fig. 1) contained relatively large amounts of 19S antibodies. 'Convalescent' sera (B, Fig. 1) contained progressively less macroglobulin until only 7S antibodies were detectable in specimens collected more than six days after measles (C, Fig. 1).

Even though measles 19S antibodies as determined by centrifugation rarely made up half the total HI activity, two-fold or greater reductions in antibody titre could be detected consistently after 2-ME treatment of sera collected during the first three weeks after immunization with live measles vaccine (Table 1). The sedimentation characteristics of that portion of the 2-ME-sensitive antibody that is not in the 19S fraction has not yet been determined. Sulphydryl sensitivity was demonstrated after treating sera with 1/10 volume 1 M 2-ME for 30 min at 37° C. Tests on treated and untreated samples were done in duplicate and in parallel and scored from 0 to 4-plus for haemagglutination. Using 2-plus agglutination as end-point, reproducibility in replicate titrations was within 0.5 log<sub>2</sub> and two-fold reductions in titre could regularly be confirmed.

Results obtained by determining sensitivity of mumps HI antibodies and Coxsackie neutralizing antibodies in sera collected after natural infection were similar to results with measles (Table 2). Titres of these antibodies in sera from healthy adults showed no 2-ME sensitivity, whereas acute and early convalescent sera from patients were uniformly sensitive to 2-ME. As in measles, titre reductions after mumps were consistent but never more

han four-fold. In the Coxsackie system reductions up to 4-fold were found.

Secondary immune responses were elicited in measles-immune persons by injection of inactivated measles vaccine. Following immunization 7S antibodies increased, but no 19S antibodies were detectable. Thus, the primary character of an antibody rise may be determined.

I thank Dr. Samuel Karelitz, Dr. Francis Black and Dr. Mary Gabrielson for providing many of the patients' sera tested.

### Simplified Procedure for Passive Haemagglutination Tests with Protein Antigens

FOR passive haemagglutination tests with proteins, it has been necessary to couple these antigens to erythrocytes by agents such as *bis*-diazotized benzidine<sup>1-3</sup>, polyene-2,4-diisocyanate<sup>4</sup> and tannic acid<sup>5</sup>. During the course of investigations with formalin-treated erythrocytes, we observed that bovine serum albumin (BSA) could adsorb on formalin-treated chicken erythrocytes (FCE), as well as on formalin-treated sheep erythrocytes (FSE) without recourse to such coupling agents. This finding suggested a means of simplifying the procedure for coating erythrocytes with proteins for passive haemagglutination tests.

When protein antigens are adsorbed on tannic acid-treated erythrocytes, Coombs's serum cannot be used since globulins of the antiserum are non-specifically adsorbed. This is overcome by preliminary incubation of the coated, tanned erythrocytes with normal serum of the different species from that providing the direct anti-protein serum<sup>6</sup>. The present method is advantageous in that Coombs's serum reacts specifically with the coated erythrocytes that have previously reacted with specific anti-protein serum and greatly augments the sensitivity of the test. Chicken erythrocytes were obtained from White Leghorn hens 20 weeks old. FCE were prepared according to the method of Weinbach<sup>7</sup> and resuspended in 0.1 M acetate buffer, pH 5.0. FCE were coated with BSA by mixing 5 ml. of 2 per cent FCE suspension with 5 ml. of acetate buffer containing 1 mg of BSA and the mixture was kept at 24° C for 4 h with constant rotation. The cells were then washed 3 times and resuspended in 0.1 M phosphate buffer, pH 7.2, as a 1 per cent suspension.

Haemagglutination tests were performed by incubating, for 1 h, mixtures of 0.1 ml. of 1 per cent BSA-coated FCE and 0.1 ml. of appropriate dilutions of chicken anti-BSA

Table 2. SPECIFIC INHIBITION OF HAEMAGGLUTINATION REACTION OF BSA-COATED FCE BY BSA

Anti-BSA serum was incubated with BSA or HGG followed by addition of BSA-coated FCE. After recording the titre, Coombs's serum was added.

BSA added	Antiserum dilution titre	
	Before Coombs's	After Coombs's
None	1/400	1/40,000
0.03 µg	1/120	1/12,000
0.1 µg	1/120	1/12,000
1.0	1/20	1/40
3.0	> 1/20	> 1/20
HGG added		
500 µg	1/400	1/40,000

serum diluted in phosphate buffer containing 2 per cent normal rabbit serum. After the agglutination reactions were recorded, 0.1 ml. of Coombs's serum (rabbit anti-chicken γ-globulin serum) was added, the tubes were shaken and then incubated for an additional hour. As shown in Table 1, before and after the addition of Coombs's serum, the chicken antiserum used gave titres of 1/600 and 1/60,000, respectively. FCE coupled with BSA via *bis*-diazotized benzidine gave the same antiserum titres.

Inhibition of the reaction by BSA, but not by human γ-globulin (HGG), attests to the specificity of the reaction. BSA in amounts ranging from 0.01 to 3 µg were incubated with 0.1 ml. of the antiserum for 0.5 h; 0.1 ml. of the reaction mixture was then reacted with 0.1 ml. of coated FCE. The data in Table 2 show that the reaction with antiserum was completely inhibited by 3 µg of BSA whereas even 500 µg of HGG was without effect.

Preliminary experiments have shown that two other antigens would coat formalin-treated erythrocytes. Using the foregoing procedure, rabbit γ-globulin was found to coat FCE as well as FSE. Ovalbumin coated FCE at pH 4 but not at pH 5.

### Quantitative Estimation of the Reactivity of Normal and Hodgkin's Disease Lymphocytes with Thymidine-2-<sup>14</sup>C

SINCE lymphoid blood cells play an important part in the mediation of delayed hypersensitivity and homograft rejection<sup>1-4</sup>, it is reasonable to expect that further understanding of these forms of immunological responsiveness will come from appropriate *in vitro* investigations of circulating lymphocytes. Lymphocyte reactivity *in vitro* may also provide insight into the pathogenesis of diseases involving immune or autoimmune mechanisms and provide a measure of the efficacy of immunological suppression. It has been the particular goal of several laboratories<sup>5-7</sup> to apply such lymphocyte investigations to the

problem of donor selection for human organ transplantation, and for this purpose several techniques for the culture of lymphocytes and the measurement of their reactivity have been developed. Inasmuch as the methods being used to determine human lymphocyte reactivity, that is, conversion of lymphocytes to large immature cells<sup>5,6</sup>, counting of mitoses<sup>5,6</sup> and autoradiography with tritiated thymidine<sup>6</sup> are laborious and subject to several sources of error, a simple quantitative technique for following lymphocyte reactions *in vitro* would be of considerable value. The present communication describes such a method which is based on the incorporation of <sup>14</sup>C-labelled thymidine into the deoxyribonucleic acid (DNA) of reacting cultured lymphocytes. This method was developed to investigate the lymphocytes of patients with Hodgkin's disease, a condition in which delayed type (cell-mediated) hypersensitivity and homograft rejection are regularly depressed<sup>8</sup>.

The technique of Bain, Vas and Lowenstein for human lymphocyte culture has been closely followed<sup>5</sup>. Heparinized venous blood was allowed to sediment for 60 min at 37° and then centrifuged at 25g for 5 min at room temperature. Into each tube 1 ml. buffy coat (or for mixed cultures 0.5 ml. of buffy coat from each of two individuals) was placed and diluted with 3 ml. of TC-199 medium containing 100 units of penicillin and 100 µg of streptomycin per ml. (obtained from Microbiological Associates, Bethesda, Maryland). Total and differential counts were done on the buffy coat by standard haematological technique, and the lymphocytes were found to constitute 30–80 per cent of the leucocytes. Because heavy aggregates form when Hodgkin's sera are cultured, the buffy coat from these individuals was centrifuged at room temperature for 5 min at 800g and the cells resuspended in an equal volume of normal human serum before diluting. After 5 days' incubation at 37° in 20 × 125 mm screw-cap glass culture tubes, 2 µc. of thymidine-2-<sup>14</sup>C in 15.9 µg (specific activity 30.5 µc./µmole, obtained from the New England Nuclear Corporation, Boston, Mass.) was added to each tube. Following an additional 90-min incubation at 37° C, the tubes were chilled and centrifuged in the cold (2° C) for 5 min at 1,300g. The lymphocyte pellet was then washed three times by resuspension in 4 ml. of cold 0.9 per cent sodium chloride and recentrifugation under the same conditions. 4 ml. cold isotonic saline was next added and the pellet homogenized briefly with an all-glass Potter-Elvehjem homogenizer. A 0.5 ml. portion of the homogenized lymphocyte preparation was then pipetted into a 'Millipore' microanalysis filter holder fitted with a 24-mm 'HA Millipore' filter disk and the cells trapped by vacuum filtration. The cells were then washed in place on the filter disk with 5 aliquots (5 ml. each) of cold trichloroacetic acid. Once the filter disks were dry they were mounted on "Tracerlab E-7B" rings and disks which were in turn placed on planchet holders and assayed for radioactivity in a Nuclear-Chicago thin end-window low background counter.

Preliminary results established that the uptake of <sup>14</sup>C-thymidine under the conditions of the incubation of five-day cultures was linear for 2.5 h and that duplicate analyses from the same culture checked to within ± 5 per cent. All cultures were performed in duplicate and separately analysed. While under certain conditions, found in incubations which contained phytohaemagglutinin (PHA), variations of ± 25 per cent were seen in duplicate cultures, in most circumstances under which the cells were investigated (unstimulated, mixed culture and after antigen addition) results from the two cultures checked within ± 10 per cent. The results of the duplicate cultures were averaged for inclusion in Table 1. An occasional grossly contaminated tube, indicated by change in colour of the indicator dye, was discarded.

The results with normal and Hodgkin's disease lymphocytes are presented in Table 1. The Hodgkin's patients

\* Reactivity is expressed in c.p.m. per  $1.25 \times 10^6$  lymphocytes. The si in parenthesis in the tuberculin column represents the status of the conventional tuberculin test (0.1 ml. of 1 to 1,000 old tuberculin intracutaneously).  
† Mixed Hodgkin's/normal lymphocyte cultures.

were the same individuals whose cutaneous anergy (depressed delayed hypersensitivity) had been established in an earlier work<sup>9</sup> by failure to accept sensitization with dinitrochlorobenzene. The results are expressed in c.p.m. per  $1.25 \times 10^6$  lymphocytes. Prior autoradiography confirmed the results of others<sup>5,6</sup> that few granulocytes survive in 5-day cultures, and that thymidine incorporation is solely within lymphocytes.

A small but measurable rate of incorporation of thymidine is seen in the unstimulated (control in Table 1) normal cultures which is increased fifty- to three hundred-fold on addition of phytohaemagglutinin (0.1 ml. Bacto-phytohaemagglutinin 'M', Difco Laboratories, Detroit, Mich. Resting incorporation by cells of a particular individual on repeat determinations displays some variability. Lymphocyte reactivity (thymidine incorporation) is markedly stimulated in mixed cultures of normal human lymphocytes over that of the individual normal control and PPD ( $2 \times 10^{-4}$  mg of purified protein derivative of tuberculin, Lilly) stimulates thymidine incorporation in individual normal cultures. While PPD stimulation correlates with tuberculin status, it is not certain that the stimulation is antigen-specific since the group of individual investigated is small (preliminary results suggest that for individuals with no history of prior antigen exposure typhoid vaccine stimulated the lymphocytes).

The response pattern of lymphocytes from anergic Hodgkin's disease patients is variable. Some show a normal response (resting, PHA, mixed culture and antigen stimulation), but most Hodgkin's individuals display depressed lymphocyte reactivity under one or more of the conditions under investigation. Thus the lymphocyte of 6 of the 10 Hodgkin's patients show depressed reactivity to PHA, and 3 of the 5 mixed Hodgkin's lymphocyte cultures show little stimulation. Likewise, the degree of PPD stimulation was minimal in the Hodgkin's lymphocytes with one exception. It is of interest that Hodgkin's lymphocytes tend to be unreactive in a number of circumstances. Since in this condition there is a defect in delayed hypersensitivity<sup>8</sup> and since there is a considerable body of evidence that lymphoid cells are concerned with the mediation of this form of immunological responsiveness<sup>1-4</sup>, this finding is not unexpected. The results are also in keeping with observations, to be reported separately.

tely, that local skin reaction following transfer of Hodgkin's lymphocytes is depressed<sup>10</sup>. Though details of the mechanism remain obscure, the immunological defect of Hodgkin's disease does appear to reside in the lymphocyte.

The technique described here offers a simple quantitative method for the evaluation of human lymphocyte reactivity. Without a substantial body of data correlating *in vitro* lymphocyte reactivity with specific sensitivity of the donor individual, the immunological significance of the former must remain in doubt. The published data at present available are inconclusive in this respect<sup>6,11</sup>. It is evident that mitosis, deoxyribonucleic acid synthesis, or large cell transformation of immunologically competent cells, cannot be equated to immunological reactivity; that is, immunologically competent cells can react to non-immunological stimuli. This conclusion in no way negates the importance of information to be gained from *in vitro* investigations of human lymphocytes, or the great significance of cell proliferation in immunological reactivity<sup>12</sup>; it merely indicates that the new information so gained must be carefully integrated into the existing body of immunological data. The technique described will perhaps make this process less difficult.

This investigation was supported by U.S. Public Health Service research grant CA-07179 from the National Cancer Institute.

## PATHOLOGY

### Lack of Diurnal Variation in Tritiated Thymidine Labelling Index of Human Leukaemic Blast Cells

VARIOUS renewal systems of mammalian cells exhibit diurnal variations in proliferative activity as evidenced by rhythmical fluctuations in mitotic index and labelling index (percentage of cells labelled) after 'flash-labelling' with tritiated thymidine. In other tissues, it is not possible to demonstrate such variations<sup>1-4</sup>. In general, it appears that diurnal variations in proliferative activity are found in cell systems with a low rate of cell renewal but not if the cell renewal rate is high. In tumours, diurnal variations in mitotic index have been reported<sup>5</sup>, but in other investigations such fluctuations have not been demonstrated<sup>1,6</sup>. In some animal tumours, the specific activity of deoxyribonucleic acid (DNA) after tritiated thymidine labelling is higher at night than during the day<sup>7</sup>, thus indicating diurnal changes in rate of DNA-synthesis per cell, changes in fraction of total cells in DNA-synthesis, or both.

The purpose of the work recorded here was to determine whether there is any diurnal variation in the proliferative activity of human leukaemic cells. The existence of such

variations would imply partial reinterpretation of data on the kinetics of leukaemic blast cells after labelling with tritiated thymidine *in vivo*, since in these investigations<sup>8</sup> the tracer was injected in the morning hours. Moreover, anti-leukaemic chemotherapy might be rendered more effective if medication was scheduled to yield maximal drug concentration during possible peaks of DNA-synthesis.

Four patients with untreated acute leukaemia were studied. From each patient, five blood samples were drawn 6 h apart during a 24-h period. 3-5 ml. of blood was immediately transferred to a test-tube containing 50 i.u. of heparin (containing no preservative), 1.0 ml. of 6 per cent dextran in saline and 2  $\mu$ c. of tritiated thymidine (1.9 c./mmole, Schwarz BioResearch, Inc.). The tube was incubated at 37° C for 50 min. Then the supernatant plasma was removed and briefly centrifuged to obtain a white cell concentrate. After exposure for 1 h to tritiated thymidine, smears of the cell concentrate were prepared; these were fixed in absolute methanol and processed for autoradiography with Kodak 'NTB-2' emulsion. After exposure for 1 week, the slides were developed and stained with Giemsa at pH 5.75. All slides from one experiment were processed simultaneously. Cells with five grains or more were considered labelled. Since the autoradiographs were deliberately over-exposed, most labelled cells had 50 grains or more, and overlap between 'labelling' due to background and true labelling did not occur. At least two slides from each sample were evaluated, and the percentage of labelled cells was determined from a total count of 1,000-4,000 blast cells. All counts were made by one observer on slides which were coded until the counting had been completed.

Table 1

2:15	2.2	3:30	6.1	11:55	2.1	14:30	6.3
8:20	1.6	9:15	6.6	17:55	2.1	20:25	6.5

Percentage of circulating leukaemic blast cells labelled with tritiated thymidine *in vitro* at various times of the day. Patients' initials (italics), sex (in parenthesis), age and type of leukaemia are included. ALL=acute lymphoblastic leukaemia, AML=acute myeloblastic leukaemia. N=number of blast cells counted at each time interval.

It can be seen from Table 1 that the labelling index of leukaemic blast cells in the blood shows no diurnal variation. Similar investigations on bone marrow blast cells have not as yet been possible because of patients' reluctance to submit to repeated bone marrow aspirations. An interesting difference between blast cells in the marrow and in the blood is that, with few exceptions, the former have a higher labelling index than the latter<sup>8,10</sup>. It is improbable, however, that this is a fundamental difference between blast cells in different sites. The most likely explanation of the observed difference is that, in part, leukaemic blast cells have lost the capacity to divide further and that the non-proliferating cells are preferentially released from the marrow, similar to the conditions pertaining to normal haemopoiesis. In this way the ratio of non-proliferating:proliferating cells becomes higher in the blood than in the marrow, which explains the observed differences in labelling indices without invoking differences between proliferating cells in various sites<sup>9</sup>. Experimental evidence exists to show that human leukaemic blast cells can enter the blood before going into mitosis after they have been labelled with <sup>3</sup>H-thymidine extravascularly, that is, they enter during the latter part of their DNA-synthesis period or during the G<sub>2</sub>-period<sup>8</sup>. Together with the fact that DNA-synthesizing blast cells are present in the blood, this indicates that cells can enter the blood while they are traversing the generative cycle.

Therefore one would expect that significant variations in the labelling index of bone marrow blast cells would be reflected by the labelling index in the blood. It is likely, then, that the lack of diurnal variation in the labelling index applies to all leukaemic blast cells irrespective of where they are located.

This investigation was supported by a research grant (CA 5492) from the National Cancer Institute, U.S. Public Health Service.

### Pathological Excretion of 4-Hydroxy-3-methoxyphenyllactic Acid

ONE of the 'spots' frequently appearing on paper chromatograms of the phenolic acids in human urine has been examined in these laboratories for some six years, since it was recognized as being of complex nature. Normally it appears to consist of a mixture of 4-hydroxy-3-methoxy- and 3-hydroxy-4-methoxyphenylhydracrylic acids, both probably largely derived from dietary chlorogenic acid, the latter isomer sometimes being observed in relatively large amounts following the consumption of citrus fruits containing the flavonoid hesperidin<sup>1</sup>. However, at least two other strongly acidic substances having rather similar  $R_F$  values have occasionally been detected, particularly in extracts prepared from urines which have been refluxed with acid in order to destroy the hydracrylic acids. The chromatographic properties of these compounds are recorded in Table 1.

Table 1. CHROMATOGRAPHIC PROPERTIES OF 3 PHENOLIC ACIDS

	3-Hydroxy-4-methoxyphenyl-hydracrylic acid	Compound A	Compound B (4-hydroxy-3-methoxyphenyl-lactic acid)
$R_F$ in anisole-acetic acid-water (70:29:1)	0.34	0.33	0.34
$R_F$ in benzene-propionic acid-water (125:72:3)	0.15	0.12	0.14
$R_F$ in dioxan-methyl isobutyl ketone-pyridine-water (40:40:12:20)	0.44	0.30	0.32
$R_F$ in isopropanol-ammonia-water (8:1:1)	0.31	0.35	0.35
Colour with diazotized <i>p</i> -nitroaniline	Violet-blue	Blue	Grey
Colour with diazotized sulphanilic acid	Red-orange	Violet-red	Violet-red
Colour with 2:6-dichloro-quinone chloroimide-borax	Blue	Blue	Negligible

Compound A was investigated in a case of neuroblastoma in which it was excreted in relatively large quantity. A similar spot has been detected in only one other subject, a case of post-operative stress maintained on a noradrenaline drip. The possibility that the substance is a drug metabolite cannot be excluded.

Compound B was particularly prominent in the case of malignant phaeochromocytoma previously reported<sup>2</sup>. Its chromatographic properties are identical with those of 4-hydroxy-3-methoxyphenyllactic acid, itself conveniently isolated as its sodium salt after reduction of

4-hydroxy-3-methoxyphenylpyruvic acid in aqueous ethanol with sodium borohydride. The acid was detected in small amount, in only one other of 30 phaeochromocytoma urines examined. However, this metabolite 3:4-dihydroxyphenylalanine was also detected readily in one case of neuroblastoma and small amounts appear to be excreted in 5 of 10 further cases of this condition (cf. ref. 3).

A variety of pathological urines have been examined for the presence of 4-hydroxy-3-methoxyphenyllactic acid using diazotized *p*-nitroaniline for its detection after paper chromatography<sup>4</sup> of extracts of acid hydrolysed urine equivalent to 1 min excretion or to 1 mg of creatinine excreted. The acid was thus detected in 2 cases of cancer one of gross kidney deficiency and one of rheumatoid arthritis in a total of 72 subjects. The foregoing urines were selected, usually because abnormalities in phenol acid excretion were revealed, from a much larger series which were examined without recourse to acid treatment many such urines did not contain interfering hydracrylic acids, but in none of these was the lactic acid detected. It has not yet been encountered in any normal urine or in urines from subjects under stress. Nevertheless its presence in traces in all urines may be inferred since the closely related 4-hydroxy-3-methoxyphenylpyruvic acid appears to be invariably present in small quantities detectable as the derived hydantoin formed by condensation with urea under acid conditions. However, excretion of the lactic acid in readily detectable amount seems to be a very uncommon phenomenon which is particularly if not invariably, associated with the abnormal production of 3:4-dihydroxyphenylalanine; it also appears to be usually associated with high excretion of *p*-hydroxyphenyllactic acid.

Allowance for possible confusion with compound B should be made if 4-hydroxy-3-methoxyphenyllactic acid is to be detected on paper chromatograms with diazonium reagents only. In particular, the grey colour obtained with diazotized *p*-nitroaniline (Table 1) may be distinctly blue if the coupling is not carried out under alkaline conditions. Compounds identified as the lactic acid have been reported to yield 'blue-violet'<sup>5</sup> or 'light blue' colours by other workers.

### Enhancing Effect of Thymectomy on Hepatotumorigenesis in Swiss Mice following Neonatal Injection of 20-Methylcholanthrene

UNTIL recently, liver has proved refractory to tumour induction by carcinogenic hydrocarbons. Klein<sup>1</sup> reported in 1959 that the increased incidence of liver tumours was attained by initiating repeated oral administration of 3-methylcholanthrene in suckling mice 7-9 days of age. Kelly and O'Gara<sup>2</sup> also noted that liver tumours were found in 6 of 11 male C3H mice after a single subcutaneous injection of 3-methylcholanthrene at birth.

Many tumours induced by chemical carcinogens are antigenic in the syngeneic and even autochthonous hosts<sup>3</sup>. This led to the concept, as noted by Miller *et al.*<sup>4</sup>, that "tumour progression might be possible only when the host's mechanism for homograft immunity is either poorly developed or depressed as a result of irradiation or of the chemical carcinogen itself". Depression of immun

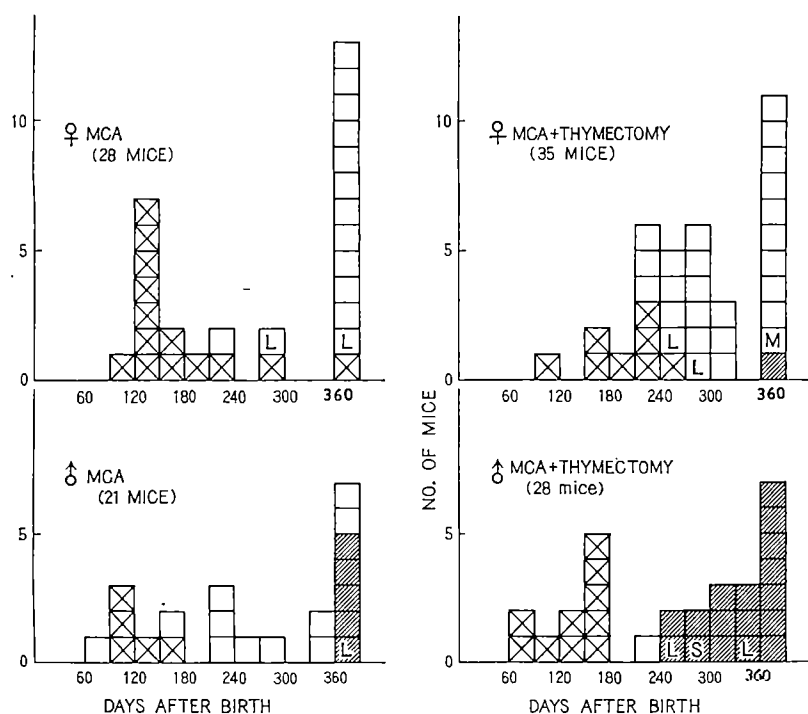

Fig. 1. Distribution of tumours in thymectomized and non-thymectomized mice injected with 20-methylcholanthrene at birth. Liver tumour; Subcutaneous sarcoma; Lymphoma; Mammary tumour; Liver tumour + lymphoma; Liver tumour + subcutaneous sarcoma.

sponse is noticed in animals exposed to carcinogenic chemicals<sup>8-9</sup>. The development of a normal immune system is dependent on the function of the thymus. The absence of the thymus during the postnatal period produces a depression of immunological reaction<sup>9-11</sup>. Because the thymus is involved in the immune reaction, it might be expected that the incidence and growth-rate of tumours would be changed in thymectomized animals. Miller *et al.*<sup>5</sup> reported that skin tumours induced by 4-benzopyrene appeared more frequently and rapidly, and became malignant in higher frequency, in mice that were thymectomized 3 days after birth than in sham-operated mice. Perri *et al.*<sup>12</sup> also demonstrated that transplantable Jensen sarcoma grew at a significantly lower rate in neonatally thymectomized rats than in normal rats. It was therefore decided to examine the effect of thymectomy on the induction of liver tumours by carcinogenic hydrocarbons.

A total of 112 new-born Swiss mice bred in this laboratory were used. Each mouse received one injection of 0.1 µg of 20-methylcholanthrene (MCA) within 24 h of birth. MCA, dissolved in 0.03 ml. of 1.0 per cent gelatine solution, was injected into the subcutaneous tissue of the terascapular area. The mice were weaned at 25 days and segregated according to sex. Sixty-three mice were

thymectomized at the age of 35–55 days. The remaining 49 mice were used as non-thymectomized controls. Another 79 mice without MCA-injection were used as non-treated controls. When animals were moribund from development of subcutaneous sarcoma at the site of injection or other causes, they were killed. Survivors were killed at 360–365 days of age. All the animals were autopsied and the different organs carefully examined for macroscopic tumours. The final diagnosis in every instance was based on microscopic examination. At autopsy, the liver was inspected for tumour nodules and the number of nodules visible on the surface was recorded. No tumour was included which did not measure at least 2 mm in diameter. The lungs, after fixation in formalin solution, were inspected for tumour nodules under a magnifying glass ( $\times 10$ ), and the number of surface nodules per lung was recorded. Then the lungs were cut into slices about 1 mm in thickness, and inspected for tumour nodules not detected on surface inspection.

Different types of tumours, including liver tumour, pulmonary adenoma, lymphoma, and subcutaneous sarcoma at the site of injection, were observed among the thymectomized and non-thymectomized mice treated with MCA at birth (Table 1 and Fig. 1).

Liver tumours developed in one male mouse among 79 non-treated control mice of both sexes, and in 5 among 21 non-thymectomized male mice killed at 360–365 days of age. In the thymectomized mice, liver tumours were observed in 17 of 28 males, and, in sharp contrast, only 1 of 35 females. All the males surviving more than 244 days of age bore liver tumours. None of 11 males that died or were killed before 225 days had liver tumours; 10 mice died of subcutaneous sarcomas, and one huge pulmonary adenomatosis. Liver tumour in one female mouse was solitary and rather small. In most instances liver tumours appearing in the males were multiple, an average of 5.3 per mouse. The fact that male mice are more susceptible to the induction of liver tumour than female mice has previously been reported in hepatotumorigenesis following exposure of infant and new-born mice to 3-methylcholanthrene<sup>1</sup>, urethan<sup>13,14</sup>, or 2-acetylaminofluorene<sup>15</sup>. This is true both in thymectomized and non-thymectomized groups after a single injection of MCA at birth. Among 17 males with liver tumours, 8 were killed or died, mostly due to weakness and dyspnoea, probably caused by the development of multiple pulmonary adenomas, 2 had liver tumours combined with lymphoma of node origin, and one bore subcutaneous sarcoma at the site of injection. The remaining 7 males were killed at 360–365 days of age and all had liver tumours. It seemed

Table 1. TUMOURS IN SWISS MICE GIVEN 20-METHYLCHOLANTHRENE (MCA) WITHIN 24 H OF BIRTH

\* Mean tumour count (total number of liver tumours/total number of mice bearing liver tumour).

† Mean nodule count (total number of pulmonary adenomas/total number of mice bearing pulmonary adenoma).

clear that all males after combined treatment (MCA-injection plus thymectomy) developed liver tumours unless they died of subcutaneous sarcoma or pulmonary adenomatosis. The gross and microscopic appearance of liver tumours was similar to spontaneous liver tumours usually described as hepatomas, which appeared sporadically in many strains of mice<sup>16</sup>. Metastatic foci of liver tumours have not so far been observed. Transplantation was not attempted.

Pulmonary adenoma is one of the tumours most frequently induced in mice following neonatal administration of carcinogenic hydrocarbons<sup>1,2</sup>. In the present investigation, all the mice treated with MCA had multiple pulmonary adenomas. The incidence did not differ between the thymectomized and non-thymectomized groups. However, the number of adenomas was larger in the thymectomized group than in the non-thymectomized group. Because the number of adenomas is related to age<sup>2</sup>, more extensive data are needed to show whether thymectomy has a promoting effect on the development of induced pulmonary adenomas. No suggestion concerning the promoting effect of thymectomy on the development of either subcutaneous sarcoma or lymphoma has so far been obtained.

The evidence that tumours possess tumour specific antigenicity has been reported from other laboratories<sup>3,4</sup>. The data reported by Prehn<sup>6</sup> show that MCA, when given to animals in the usual way for tumour production, can indeed interfere with a weak immune reaction. Thymectomy performed shortly after birth is followed by a marked depression of immunological reaction during the postnatal period, including the skin homograft rejection mechanism<sup>9-11</sup>, and morphologically, by a severe depletion of the development of lymphatic tissue<sup>9-11,17</sup>. The regression of lymphatic tissue is also produced in mice thymectomized at 4-6 weeks of age<sup>18</sup> and at 35-45 days<sup>19</sup>. Therefore, it may be assumed that the combined treatment, MCA-treatment plus thymectomy, exhibits synergism in depressing the immune response which, in turn, facilitates the early and frequent development of spontaneous liver tumours. It may also be possible that the latent tumour cells produced by an action of MCA grow faster and form visible tumours in the host with a weakly depressed immune response resulting from thymectomy. It may be that interference with the immune mechanism plays an important part in tumorigenesis.

## BIOLOGY

### Annual Cycle in the Size of the Gut of the Purple Sea Urchin, *Strongylocentrotus purpuratus* (Stimpson)

SEVERAL species of sea urchins undergo an annual reproductive cycle with a seasonal enlargement and shrinkage of the gonads<sup>1</sup>. In connexion with investigations on the annual reproductive cycle of the purple sea urchin, *Strongylocentrotus purpuratus*, it was found that the gut of the urchin also undergoes a seasonal cycle in size.

Twenty urchins were collected monthly from a tide pool near Yankee Point, California (36° 33' N., 121° 57' W.). The gut, exclusive of the pharynx, was dissected from each urchin, washed free of its contents, drained of free water and weighed. The gonads were also removed, drained and weighed. Both organs were then dried and reweighed to determine their water content. The relative sizes of the gut and gonads to the entire urchin were expressed as the gut index ( $\frac{\text{wet weight of gut}}{\text{wet body-weight}} \times 100$ ) and gonad index ( $\frac{\text{wet weight of gonad}}{\text{wet body-weight}} \times 100$ ) respectively.

The entire cycle in the size of the gut can be seen in Fig. 1. In both sexes the gut index increases in the summer, reaching a maximum in the autumn, and then decreases, reaching a minimum in the winter. This change did not result from changes in the water content of the gut tissue as the percentage of water remained constant throughout the year (Table 1).

The variation in the gut index can possibly be correlated with the amount of food ingested by the urchin. A seasonal change in the feeding behaviour of the urchin *Strongylocentrotus intermedius*, which consumes more food during the spring, has been described by Fujii<sup>2</sup>. Seasonal fluctuations in the amount, kind, or composition of marine algae available to the urchins in the intertidal region may also be factors.

Supporting the interpretation that the food consumption of the urchin affects the size of the gut are the data in Fig. 1, which show that urchins starved in the laboratory have low gut indices, and that continuous feeding of previously starved animals on the brown alga *Macrocyst pyriformis* can stop the decline in the size of the gut.

The histogram (Fig. 2) demonstrates that the decrease in the gut indices of starved animals is due to a decrease

1 the thickness of the epithelial layer lining all major regions of the digestive tract. Fuji<sup>3</sup> concluded from histochemical evidence that the inner epithelium of the stomach and intestine of *S. intermedius* possesses reserves of lipid and glycogen which decrease appreciably after starvation or five weeks. The seasonal cycle in the gut index is also probably due to fluctuations in the thickness of the epithelium lining all regions of the digestive tract.

These results support the contention that the gut, in addition to its digestive and absorptive functions, acts as a storage organ, a suggestion made by previous workers<sup>1,3,4</sup>. Whether the gut plays a part in storing nutrients for transfer to the gonads for gametogenic purposes, as has been indicated for the digestive gland in sea stars<sup>5-7</sup>, is

Fig. 3. Seasonal variation (January 1963 until March 1964) of the gonad index of *S. purpuratus*. The points and vertical lines represent means and  $\pm 1$  S.D.

undetermined, but is perhaps suggested by the manner in which the gonad cycle (Fig. 3) lags behind that of the gut.

Fig. 2. The effect of starvation and feeding on the thickness of the gut wall of the *S. purpuratus*. The bar on the left for the tall interradial sectors of pharynx, the oesophagus, the first festoon of the stomach, and the third festoon of the intestine represents the average thickness of the gut wall for 10 sea urchins fed *Macrocyrtis* continuously from March 22, 1963, until June 3, 1963; that on the right, the average for 10 sea urchins starved from April 12, 1963, until August 27, 1963. The average weight of the fed and starved urchins was 25.3 and 26.5 g, respectively. Measurements were made on 7  $\mu$  cross-sections of gut fixed in sea-water Boulin's and stained with periodic acid Schiff-haematoxylin. The difference between the fed and the starved group in the thickness of the lining epithelium (shown  $\pm 1$  S.D.) is significant at the 0.01 degree level for all gut regions. There is no significant difference between the fed and the starved groups in the thickness of the connective tissue-muscle layer or visceral peritoneum in any of the gut regions.

## A Beaked Whale New to the Western Hemisphere

A 16-ft. female beaked whale of the genus *Mesoplodon*, family Ziphiidae, drifted ashore at Delmar, about 15 miles north of San Diego, California, on June 10, 1954. One of us (R. M. G.) made body measurements, drawings, and photographs of it, and preserved the skull and jaw. The specimen was presented to the United States National Museum where it is catalogued as No. 298237, but was temporarily retained for examination. Because the specimen could not then be identified to species, this material was laid aside and, in the pressure of other affairs, forgotten. After one of us (J. C. M.), in order to revise the genus *Mesoplodon*, had completed a tour of most museums of the world known to possess specimens, he was invited to investigate this Delmar specimen to include data from it in his revision.

Nishiwaki and Kamiya<sup>1</sup> described a new species of *Mesoplodon* from a specimen stranded on Oiso beach near Tokyo, Japan, on September 22, 1957, naming it *Mesoplodon ginkgodens*. Although those authors<sup>1,2</sup> splendidly documented their specimen with measurements and photographs, they had only one skull of an adult specimen and principally photographs and published measurements to compare it with, and were able to offer no diagnosis. Moore<sup>3</sup> reviewed at length the evidence that invalidates

the first dichotomy of the key that Nishiwaki and Kamiya<sup>2</sup> did present, and has since<sup>4</sup> produced a key to the seven species of *Mesoplodon* inhabiting the northern hemisphere based on original study of 42 specimens in North American museums. The characters of that key which distinguish the species *M. ginkgodens* identify the Delmar specimen as *M. ginkgodens*. (1) When the skull is upright with the long axis of the beak horizontal, the anterior view shows at least one of the pair of premaxillary foramina to open on or below a 'horizontal' plane (paralleling the long axis of the beak) that transects the centres of the maxillary foramina. (2) The length of vomer visible on the palate is greater than 100 mm. (3) In lateral view of the antorbital tubercle, the lacrimal is relatively thick (Pl. III, Nishiwaki and Kamiya<sup>2</sup>) and does not curl up around the anterior end of the frontal bone (Fig. 13, Raven<sup>5</sup>).

This is the first record of *Mesoplodon ginkgodens* for the eastern North Pacific, for North America, and for the western hemisphere. It is the third species of *Mesoplodon* to be known for the western coast of North America, and the seventh species to be known from the coasts of the North American continent<sup>4</sup>.

Deraniyagala<sup>6,7</sup> described a specimen of *Mesoplodon* stranded at Ratmalana, Ceylon, on January 26, 1963, and gave it a new name, *M. hotaula*. He did not compare it with the excellently illustrated details of the type of *M. ginkgodens* published by Nishiwaki and Kamiya<sup>1,2</sup>. Moore has since measured and studied in great detail both the Ratmalana specimen and the type of *ginkgodens*, and finds that the former is like the latter in virtually every feature of the skull except those commonly distinguishing between the sexes in this genus. The foregoing three enumerated characters of *ginkgodens* distinguish the type of *M. hotaula* Deraniyagala, 1963, as another adult female of the species *ginkgodens*.

Since this Ratmalana specimen is from deep in the tropics, the species *ginkgodens* may yet be found in the southern hemisphere, and further diagnosis is needed to distinguish *ginkgodens* from the *Mesoplodon* species of the southern hemisphere. Without especially depleting the revisionary work to come, it seems advisable to provide here the criteria needed for identification of further specimens of *M. ginkgodens* that may be found before the revision becomes available, and we are pleased to provide for *M. ginkgodens* this more complete taxonomic description: (4) The greatest length of the right nasal bone on the vertex of the skull (69, 76 and 81 mm) is more than twice the least distance between premaxillary foramina (30, 35 and 36 mm respectively). (5) The greatest transverse span of the combined premaxillary bones at the midpoint in the length of the beak (45–49 mm) is greater than 40 but less than 60 mm. (6) The greatest width of temporal fossa approximately perpendicular to the long axis of the temporal fossa is less than 60 mm.

**Diagnosis.** The foregoing enumerated six characteristics of *Mesoplodon ginkgodens* distinguish it from all the eleven other species of the genus *Mesoplodon* as follows: from *bidens* by 1, 4 and 5; *densirostris* by 1 and 4; *europaeus* by 2 and 4; *layardi* by 6; *hectori* by 4; *grayi* by 4 and 5; *stejnegeri* by 1, 4 and 5; *bowdoini* by 6; *mirus* by 3 and 5; *pacificus* by 6; and *carlhubbsi* by 1 and 4.

It is surprising that examination by one of us of perhaps 90 per cent of the specimens of *Mesoplodon* known to be in the world's museums in 1963 has revealed no skulls of *ginkgodens* evidently taken earlier than this Delmar specimen, but this note may alert zoologists of the Pacific and Indian Oceans to the probability that more specimens will be found on other shores. Evidence has been shown (Fig. 16, Moore<sup>8</sup>) that two other North Pacific species of the genus *Mesoplodon* appear to occupy partially allopatric ranges, *stejnegeri* from about 60° to 40° north latitude and *carlhubbsi* from about 50° to 30°. Another species, *M. densirostris*, has now been reported for the North Pacific by Galbreath<sup>9</sup> from one immature and one adult female stranded on Midway Island. This species, *densirostris*,

is earlier known<sup>10</sup> from the North Atlantic, the South Pacific, and Indian Oceans, however, and it is the only one of the (twelve) *Mesoplodon* species which is now well established as an inhabitant of temperate and warm areas of oceans on both sides of the equator. Since the species ranges of which are best known, *M. bidens*, *M. europaeus*, *M. stejnegeri*, and perhaps *M. mirus*, from charts Moore<sup>4,8</sup> seem to have ranges restricted to parts of single oceans, some interest now attaches to future occurrence of *ginkgodens* on other shores.

We thank Drs. Masaharu Nishiwaki of the Whal Research Institute, Tokyo, and P. E. P. Deraniyagala, director emeritus of the National Museum of Ceylon, Colombo, for permission and generous facilities to study their type specimens in those institutions, and the U. S. National Science Foundation for grant GB 507 to one of us (J. C. M.), which enabled him to visit Colombo and Tokyo to examine the foregoing type specimens.

## Gestation Period and Neonatal Weight of the Hyrax

THE literature contains only one record of the gestation period of hyrax, namely, that of Murray<sup>1</sup>, which was for *Procavia capensis* in South Africa. Copulation was observed on April 3 and the nine-year-old female gave birth to a single young on November 21, a gestation period of 7.5 months (232 days), a little longer than a previous estimate of 6–7 months<sup>2</sup>. A recent observation on Mount Kenya hyrax (*Procavia johnstoni mackinderi* Thomas) provides confirmatory evidence. A mature female, which had been in captivity in the company of two males for nine months, showed a rise in rectal temperature at the end of March (1963), reaching a peak of 38.9° on April 6. On April 4 what appeared to be seminal fluid was present at the vulva. The female gave birth to a pair of male young on November 3, giving a gestation period of more than seven months (214 days). This suggests that there is little difference between the gestation periods of *P. capensis* and *P. johnstoni*, especially when the possibility of parturition being delayed in Murray's animal, due to it being a very old primipara, is borne in mind. The probability that the two gestation periods are the same is consistent with the anatomical evidence that all *Procavia* are races of one species<sup>3</sup>.

It is interesting to note that while the date of the birth agrees with Coe's<sup>4</sup> estimate of the breeding season of *P. johnstoni mackinderi* as between August and November the number of young does not fit in with his statement that "no animal apparently ever produces more than one young at a time". It is, however, in line with Van de Horst's experience<sup>5</sup> and my own<sup>6</sup>, for we have both stated that hyrax bears 2 or 3 young per litter. A probable explanation of Coe's observations is that they were made on a part of Mount Kenya where a very high population density reduced the litter size.

Table 1

Wt. of mother	Wt. of litter	Litter wt. $\times 100$		
		Actual	Predicted	Deviation
2,718 g	680 g	25	14.2	10.8

Although the large size of the new-born hyrax has often been commented on<sup>1,6</sup>, there are few records of birth weights. Leitch *et al.*<sup>7</sup> compared pre-mating weights of young adult females with the total weight of the newly born in 114 species of mammals and found that the larger the species the smaller (relatively) the total weight of offspring. They produced the following equation for the prediction of the weight of the young from the weight of a mother:  $N = 0.5408 M^{0.8923}$ , where  $N$  is the neonatal weight and  $M$  the maternal weight. Actual and predicted litter weights are compared with the maternal weight (average for the 6 months before mating) for the *P. johnstoni* female under consideration in Table 1. It will be seen that the actual litter weight is 10.8 per cent (of the maternal weight) greater than predicted, using the foregoing equation. The only wild mammals in the survey of Leitch *et al.* giving a greater positive deviation from the predicted value were two voles (*Microtus oeconomus timmingsi* and *M. arvalis*). The long gestation period (longer than for any other mammal of its size) and high neonatal weight of the hyrax support the palaeontological evidence that the ancestors of the modern hyrax were much larger animals<sup>8</sup>.

### Absence of Growth Effects of Thalidomide on Higher Plants

THE teratogenic effects of thalidomide (TH),  $\alpha$ -N-phthalimido-glutarimide, are well recognized and have been recorded for a number of animals<sup>2</sup>. The critical period has been found to correspond to the time of morphogenesis<sup>2,3</sup>. These drastic effects in animals raised the question of possible effects on plants. Some positive evidence for effects on lower plants was indicated by the work of Boney<sup>1</sup>, who noted that high concentrations of TH not only inhibited growth but also induced abnormalities in sporangia of a marine red alga, *Callithamnion tetricum* Ag. Giacomello *et al.*<sup>4</sup> tested the activity of high concentrations of TH in embryonic vegetal tissues of the common onion, *Allium cepa* L., and reported alterations in cell mitosis as well as the occurrence of chromosomal aberrations.

A number of naturally occurring phthalide substances bearing structural resemblances to TH are known to act as growth inhibitors of plants<sup>5</sup>. These substances, isolated from *Levisticum officinale* Koch, have inhibited germination and growth of *Lepidium*, rhizoid growth of *Marchantia* and germination of pollen of *Impatiens*. The purpose of the present work was to investigate possible growth-inhibitory effects of TH on a number of higher plants. In order to ascertain the true biological action of TH, the massive doses used by the foregoing workers were avoided.

Table 1. EFFECT OF THALIDOMIDE (TH) AND L-GLUTAMINE ON ELONGATION OF ROOTS OR EXCISED ROOTS OF *Linum*

	Controls (mm)	L-Glutamine $6 \times 10^{-3}$ M (mm)	TH $6 \times 10^{-3}$ M (mm)	L-Glutamine + TH (mm)	L.S.D. 1%
Roots of seedlings	43.9	43.1	15.5	14.3	2.94
Excised roots	12.3	12.7	6.6	6.2	1.46

Table 2. EFFECT OF THALIDOMIDE (TH) AND INDOLYL-3-ACETIC ACID (IAA) ON THE ELONGATION OF OAT COLEOPTILE (mm)

IAA $\mu$ g/ml.	0	0.04	0.04	0.04	0	0	0
TH $\mu$ g/ml.	0	0	0.50	2.50	0.55	2.58	12.90
Length of coleoptile	5.93	6.87	6.81	6.99	5.96	6.09	6.03
L.S.D. 1% 0.51							

Tomato, *Lycopersicon esculentum* Mill., barley, *Hordeum vulgare* L., and soybean, *Glycine max* Merr., seeds were germinated in pots containing quartz sand. The seedlings were thinned and triplicate pots were treated with Hoagland's solution containing TH in the following concentrations: (1) 0; (2)  $1 \times 10^{-5}$  M; (3)  $1 \times 10^{-4}$  M; and (4)  $1 \times 10^{-3}$  M. After daily treatments for 15 days the growth effects were observed and compared.

There was no noticeable response to the treatments by soybeans and very little response by barley except for a slight yellowing of leaf tips in the highest treatments. The most concentrated treatments also produced a slight effect in tomato (see Fig. 1); the plants were generally smaller, the leaves were somewhat mottled and leaf margins were curled.

Because of the known effect of TH on animal embryonic tissue, its action was investigated on tomato flowers in all stages of development and on the fruit. Spray-treatment was continued for three consecutive days with a 1:1 water:acetone solution of TH and each plant received 100 mg of TH per day. Regardless of the stage of flower development when treated, TH did not affect fruit development. In addition, the seeds from TH-treated tomato plants germinated normally.

Seeds of *Lepidium* and *Linum* were placed on filter papers in Petri dishes, moistened with several concentrations of aqueous TH and set aside to germinate. For both species the seeds germinated in the same length of time except in the case of the highest concentration of TH ( $6 \times 10^{-3}$  M). For the latter it was found that germination was delayed for a period of one day, but the percentage of seeds that germinated was unaffected.

The effect of TH on root growth of flax was tested on seedlings which had previously been germinated in water and afterwards treated with aqueous solutions of TH. After 2 days the following root-lengths (average of 4 replicates) were found: control, 40.4 mm;  $1 \times 10^{-4}$  M, 39.9 mm;  $1 \times 10^{-3}$  M, 38.6 mm;  $6 \times 10^{-3}$  M, 19.2 mm. Since the least significant difference (L.S.D.) at the 1 per cent level was 4.3, the  $6 \times 10^{-3}$  M concentration caused a significant retardation of root elongation.

The effects of TH in inhibiting the elongation of oat coleoptile were checked by co-treatment with indolyl-3-acetic acid which is known to cause such elongation. Even when the relative concentration of TH:indolyl-3-acetic acid was as high as 40:1 such inhibition was not observed (Table 2).

Fig. 1. Effect of thalidomide (TH) on growth of tomato seedlings. From left to right: control,  $1 \times 10^{-5}$  M,  $1 \times 10^{-4}$  M and  $1 \times 10^{-3}$  M of TH

Boyle *et al.*<sup>2</sup> reported that L-glutamine gave complete protection against abnormalities in chick embryos caused by certain derivatives of TH. The results in Table 1 show that co-treatment with L-glutamine produced no similar effects on seedlings or excised roots of *Linum*.

The work reported here demonstrates that TH generally does not affect the growth of higher plants. Although it is possible that it causes some slight threshold effects, the concentrations of TH required for this are about two orders of magnitude higher than in the case of certain structurally related naturally occurring phthalides.

We thank Frank W. Horner, Ltd., Montreal, for a supply of thalidomide.

## ENTOMOLOGY

### Detection of Lipids in the Honeydew of an Aphid

NUMEROUS analyses have been reported concerning the chemical composition of honeydew produced by many homopterous insects, especially members of the family Aphididae. Such compounds as fructose, glucose, sucrose and free amino-acids seem to be universally present in honeydew. Various other mono-, di-, and oligo-saccharides are occasionally found in honeydew. Proteins are apparently absent, although peptides have been reported. Miscellaneous compounds found in honeydew include several organic acids, inorganic ions, sugar alcohols and auxins, such as indolyl-3-acetic acid<sup>1</sup>. With one exception<sup>2</sup>, no reports have been located making reference to the presence of lipid material in honeydew, although it is well known that certain lipids (for example, sterols) are of great physiological importance to insects.

Between 150 and 200 mg of honeydew were collected by placing glass plates (which had been sprayed with 'Merthiolate') for 24 h under colonies of *Myzus persicae* (Sulzer) feeding on Chinese cabbage, *Brassica campestris*. The honeydew was washed from the plates with tepid water and extracted from the aqueous solution with chloroform. After evaporation of the solvent under reduced pressure and purifying the crude extract<sup>3</sup>, the amount of lipid material present in honeydew on a dry-weight basis was found to be 0.60 per cent. The purified extract was chromatographed on a silicic acid column<sup>4</sup> and the neutral lipid fraction purified by chromatography on a 'Florisil' column<sup>5</sup>. Tentative identification of the lipid classes was made by comparing the emergence of unknowns from the 'Florisil' column with known standards, and by co-chromatography of the 'Florisil' eluates with known compounds on thin-layers of silica-gel G in various solvent systems<sup>6</sup>. Free sterols and sterol esters were identified by the *L-B* reaction and by spraying the thin-layer plates with stannous chloride<sup>6</sup>. None of the thin-layer chromatography reported here was quantitated, although visual estimates of the relative amounts of the different classes of lipids were made. No work was carried out on the polar lipids eluted from the silicic acid column.

Using the foregoing methods, the major class of lipids in the honeydew samples was found to be the free fatty-acids. Gas-liquid chromatography of these free fatty-acids<sup>2</sup> revealed that palmitic acid accounted for 44 per cent of

the total. Free sterols were readily detectable in honeydew, although sterol esters were absent. Triglycerides were present, but only in minor amounts. Mono- and diglycerides could not be identified with certainty. Hydrocarbons and pigments were abundant and squalene was present in trace amounts. Two major unidentified fractions and numerous minor ones were present in all samples. The major fractions had chromatographic properties similar to hydroxy fatty acids.

The origin of the lipids found in the honeydew is not known, but it is suspected that at least some of them come directly from the host plant. A distinct correlation existed between the physiological condition of the host and the honeydew lipids. Aphids feeding on a senescent plant produced honeydew rich in hydrocarbons and pigments, but containing little or no free sterols; the reverse was true for aphids feeding on young plants.

I thank Prof. H. J. Vonk for allowing me to carry out this investigation in the Laboratory of Comparative Physiology, University of Utrecht, the Netherlands.

## VIROLOGY

### Further Observations on the Effect of 6-Aminonicotinamide on Chick Embryo Tissue Cultures infected with Vaccinia and other Viruses

I HAVE recently described the inhibitory effect of 6-aminonicotinamide (6-AN) on the growth of vaccinia virus in the chick embryo fibroblast (CEF) host cell system<sup>1</sup>. When CEF cultures were treated with 6-AN at a dose of 5 µg/ml. for an interval of 8 h at 36° C, it was found that 6-AN rendered the cells refractory to infection with vaccinia virus. This effect increased as the time of exposure to 6-AN lengthened up to 8 or 10 h before virus infection. Evidence was also obtained to show that the inhibitory effect produced by 5 µg/ml. of 6-AN could be reversed by the simultaneous addition of 5–50 µg/ml. of nicotinamide, but not if it was added at a later time. The drug did not seem to exert a direct lethal effect on the virus.

Details of techniques, including the propagation of vaccinia virus, preparation of CEF cultures and a simple fluid-overlay plaque assay technique employed throughout the experiment have been described previously<sup>1</sup>. Influenza A virus (strain 'MEL') and influenza B virus (strain 'GL') were grown in the allantoic cavity of embryonated eggs. The [strain of herpes simplex virus was one originally isolated in primary human amnion cell cultures derived from a recent case of fatal encephalitis and was propagated in HA-FL cells. Sindbis virus was grown in CEF cultures.

6-AN when diluted in Hanks's balanced salt solution (BSS) to yield a 5 µg/ml. concentration was introduced to CEF cultures grown in 19 × 25 mm Leighton tubes for periods of 6, 4, 3, 2 and 1 h before infection with vaccinia virus; and simultaneously with addition of virus; and 6, 4, 3, 2 and 1 h after addition of virus. 6-AN was also added to cultures 6 and 8 h after virus adsorption up to termination of the experiment. The cultures were washed three times with BSS before and after the addition of 6-AN

Table 1. EFFECT OF ADDITION OF 6-AN AT TIME INTERVALS, ON VACCINIA GROWTH ON CEF CULTURES

\* Immediately after exposure to virus for 1.5 h with a virus input of 2-10 P.F.U./cell at 36° C, the cell cultures were washed and re-fed with the corresponding medium. Samples were taken from each group and assayed for the amount of virus adsorbed. Results showed that  $1.0-1.2 \times 10^4$  P.F.U./ml. of virus had been adsorbed per culture.

M = Hanks's BSS.

at each time interval as well as after virus adsorption. At the end of the experiments, the corresponding cultures were collected. Infectivity was determined by plaque-forming units (P.F.U.) on CEF cultures set up in screw-capped tubes, using a fluid-overlay plaque assay technique. Table 1 demonstrates that the 6-AN does not affect virus adsorption, or prevent the release of virus. It is interesting to note that 6-AN displays only a slight difference in the extent of inhibition on growth of vaccinia virus in the CEF cultures, when the latter were exposed to 6-AN for the corresponding period of time before and after a period of 1.5 h of virus adsorption. 6-AN appears to have no marked demonstrable effect when added 6-8 h after virus adsorption.

Single-cycle growth curve experiments were performed in 6-AN-treated (5  $\mu$ g/ml. in BSS for 8 h at 36° C) and untreated CEF cultures. The cultures were infected with stock vaccinia virus with an input multiplicity of 2-10 P.F.U./cell. After 2 h adsorption, the cultures were washed three times and re-fed with BSS. At time intervals, two cultures were removed from the incubator and the content of intracellular virus was measured by P.F.U. as before. The data, as shown in Fig. 1, reveal that the vaccinia virus multiplies at different rates in the two types of cul-

tures. It would seem that in treated cultures the eclipse phase was not as marked as that observed in untreated control cultures. This result suggests that only a small proportion of the adsorbed virus may participate in the eclipse period and so replicate in the treated cultures. By using fluorescence microscopy and acridine orange staining techniques<sup>2</sup>, it was also demonstrated that the development of vaccinia virus intracytoplasmic inclusions was markedly suppressed. The mode of action of 6-AN on the growth of vaccinia virus in CEF cultures is obscure and awaits further investigation.

Additional investigations on the effect of 6-AN on other viruses in CEF cultures indicated that 6-AN also exerted a delaying effect on the growth of influenza B virus but not the influenza A virus. Cultures were observed microscopically for cytopathic effect and assayed by standard haemagglutination procedures. Similarly, no evidence of significant inhibitory effect was revealed in the case of herpes simplex and Sindbis viruses.

### Relationship between Guanidine-dependence and Neurovirulence of Poliovirus

GUANIDINE-resistance<sup>1</sup> and guanidine-dependence can be induced *in vitro* in poliovirus<sup>2,3</sup>. We have recently demonstrated that both characters can be easily conferred and withdrawn in *in vitro* experiments<sup>4,5</sup>. Moreover, we have demonstrated that guanidine-dependent viruses are not neurovirulent for monkeys<sup>6</sup>. In the present report we show that neurovirulence (of the type producing paralysis) for monkeys and guanidine-dependence *in vitro* are two strictly related viral properties.

Indeed, although guanidine-dependent poliovirus is not neurovirulent for monkeys, it reacquires this character when guanidine-dependence is reversed. The techniques used are described in ref. 7. A strain of virulent Mahoney poliovirus isolated from the spinal cord of a monkey was cloned twice and was made guanidine-dependent *in vitro* by sub-culturing it in the presence of increasing concentrations of guanidine. When this strain had acquired a high degree of guanidine-dependence, it was sub-cultured in decreasing concentrations of guanidine and finally in the absence of guanidine. The original viral strain and the two strains obtained with the foregoing procedures were injected intramuscularly into cercopithecus velvet monkeys at a dosage of  $10^6$  cytopathic units (C.P.U.) per animal. The infected monkeys were observed for signs of paralysis up to 100 days.

Fig. 1. Growth curve of vaccinia virus in 6-AN treated and untreated CEF cultures. ●, Virus grown in untreated cultures; ○, virus grown in treated cultures

Table 1. RELATIONSHIP BETWEEN *in vitro* SENSITIVITY OF POLIOVIRUS TO GUANIDINE AND ITS NEUROVIRULENCE FOR MONKEYS

Viral strain	Guanidine HCl $\mu\text{g/ml.}$ of culture medium		Neurovirulence for the monkeys		Range of onset of paralysis (days after injection)
	0	1,000	C.P.U. injected intramuscularly	No. monkeys with paralysis/No. monkeys injected	
	C.P.U. detected after 5 days at 37° C*				
CVM†	$3 \times 10^7$	$10^8$	$10^8$	5/5	4-11
CVM 70 G‡	$2.5 \times 10^5$	$7.5 \times 10^6$	$10^8$	2/2	7-8
CVM 70 G-20§	$1.2 \times 10^7$	$2.5 \times 10^5$	$10^8$	0/12	—
				6/6	5-10

\* End point method.

† CVM = Virulent Mahoney isolated from the spinal cord of a monkey paralysed after the injection of Mahoney polio I and cloned twice.

‡ CVM 70 G = CVM propagated 70 times in human amnion cells (Mascoli-line) in the presence of the following guanidine HCl concentrations ( $\mu\text{g/ml.}$ ): once, 16; once, 64; twice, 250; twice, 500; twice, 1,000; and 62 times, 2,000.§ CVM 70 G-20 = CVM 70 G propagated 20 times in human amnion cells (Mascoli-line) in the presence of the following guanidine HCl concentrations ( $\mu\text{g/ml.}$ ): twice, 1,000; twice, 250; once, 125; once, 64; once, 16; and 13 times without guanidine.

Table 1 compares the sensitivity to guanidine *in vitro* with the relative neurovirulence of the different strains used. It appears that the regression of guanidine-dependence *in vitro* is accompanied by a return of the neurovirulence *in vivo*. It is interesting to notice that guanidine-dependent poliovirus retains the cytopathogenic activity *in vitro* provided guanidine is present in the medium.

We may conclude that the guanidine-dependent poliovirus is non-pathogenic for monkeys since the concentration of guanidine required for its growth is much higher than that present in mammalian cells and fluids.

### Posterior Paralysis of Hamsters with Herpes simplex Infection of the Cervix

LITTLE has been reported about specific virus infections of the female genital tract. Most text-books on gynaecology make sparse or no reference to virus infections of the tract except for lymphogranuloma venereum in human beings. As part of an investigation of the role of 'ordinary' viruses in neoplasia of the cervical tract, an attempt was made to develop an experimental model which would enable the interrelationships of viruses and carcinogens to be studied. Herpes simplex virus was selected for initial investigation because of the relatively frequent occurrence of vesicles in the tract of women and because of the latency aspect of its pathogenesis.

The D.J. strain of herpes virus (isolated by Dr. G. Waddell from a child with stomatitis) was used in the investigation. Virus pools were prepared in primary rabbit cell cultures. Hamsters (40-60 g) were infected as follows: Vaginal tracts were first swabbed with cotton pledgets on tooth picks. A second swab which had been soaked in the virus fluid ( $10^7$  ID<sub>50</sub> per ml.) was introduced through a paediatric otoscope speculum and applied directly to the cervix.

Animals were kept under observation for viral growth in the vaginal tract and for clinical and pathological effects. Vaginal exudates were collected daily from the

tract using a swab soaked in Hanks's solution. The swabs were placed in vials containing 1 ml. of Eagle's solution with 10 per cent skimmed milk, and then quick-froze and stored until all samples could be assayed for virus at the same time. Daily samples from pairs of hamsters were pooled and each was titrated in primary rabbit kidney cells using typical cytopathic effects as a measure of the infection.

Six experiments involving 117 infected animals were carried out. Infection in most animals was characterized clinically by a moderate to heavy vaginal exudate which had appeared usually by the third day. At about the fifth to the seventh day many of the hamsters showed posterior paralysis involving both hind limbs. Such animals appeared alert and continued to eat for several days. A few died and some even recovered, but most were killed for further investigations: in all 48 hamsters (41 per cent) showed paralysis. The results of several experiments are summarized in Table 1.

Table 1. EFFECTS ON HAMSTERS OF HERPES SIMPLEX VIRUS ADMINISTERED BY WAY OF THE VAGINAL TRACT

23	10	10	6	5
Cont.*	26	3†	0	0

\* Controls were inoculated with Eagle's medium.

† Inflammatory response probably resulted from inoculation technique.

Preliminary histopathological findings include a cervicitis and vaginitis characterized by mononuclear cell thickenings of the sub-epithelial layers. In some animals epithelial microabscesses with some cells containing intranuclear inclusions were noted. Spinal cords of the few paralysed animals examined had lesions of viral myelitis involving primarily the grey matter. Lesions were not found in the brains of these animals.

Assays of vaginal washings indicated a period of low yield of virus shortly after inoculation with increasing amounts until day 5 when maximum yields of about  $10^4$  TCD<sub>50</sub> per ml. washing fluid were obtained. This was followed by a tapering off until day 12 when virus could no longer be demonstrated. Virus was also isolated specifically from the cervix of some animals by explanting tissues and growing them on 'Millipore' filters; however, the results of this will be presented in a separate report.

The observation of special interest was the development of posterior paralysis in many of the animals with vaginocervicitis. This raises the question of how the virus reached the central nervous system from the tract. The posterior involvement suggests that spread of virus was by means of local neural routes. Paralysed animals did not show signs of encephalitis. It is likely, however, that once the virus had reached the spinal cord, it spread throughout the central nervous system, thus accounting for the death. As yet investigations of nervous tissue for virus growth and spread have not been made.

Johnson<sup>1</sup> recently studied virus pathways to the nervous system of mice given herpes by several non-neural routes. His work indicated that, depending on the route of administration, the virus can enter the central nervous system by either haematogenous or neural routes. Mice given virus subcutaneously or by way of the foot pad developed posterior paralysis. As determined by immunofluorescence techniques, the virus apparently spread along nerves by infection of endoneurial cells (Schwann cells and fibroblasts). A similar pathway is suggested in the present investigation.

## FORTHCOMING EVENTS

(Meetings marked with an asterisk are open to the public)

## Monday, March 22

INSTITUTE OF ACTUARIES (in Staple Inn Hall, High Holborn, London, W.C.1), at 5 p.m.—Mr. A. J. Steeds: "Some Considerations Affecting the Selection of Risks".

IMPERIAL COLLEGE OF SCIENCE AND TECHNOLOGY (in the Main Lecture Theatre, Department of Electrical Engineering, Exhibition Road, London, S.W.7), at 5.30 p.m.—Mr. A. Wickens: "Riding of Railway Vehicles".

INSTITUTION OF CIVIL ENGINEERS (at Great George Street, London, S.W.1), at 5.30 p.m.—Informal Discussion on "Report on the Conference on Education and Training, held at Imperial College on 14/15 September, 1964" introduced by Prof. S. R. Sparkes.

INSTITUTION OF ELECTRICAL ENGINEERS, ELECTRONICS DIVISION (at Savoy Place, London, W.C.2), at 5.30 p.m.—Dr. A. P. Willmore: "Experimental Instrumentation in Scientific Satellites".

INSTITUTION OF MECHANICAL ENGINEERS, EDUCATION AND TRAINING GROUP (at 1 Birdcage Walk, Westminster, London, S.W.1), at 6 p.m.—Discussion on "New Teaching Techniques in Engineering Laboratories".

ROYAL GEOGRAPHICAL SOCIETY (at 1 Kensington Gore, London, S.W.7), at 6 p.m.—"Films of the Far East" (Colour films).

## Monday, March 22—Friday, March 26

OIL AND COLOUR CHEMISTS' ASSOCIATION (in the Great Hall of Alexandra Palace, London, N.22)—Seventeenth Technical Exhibition.

## Tuesday, March 23

SOCIETY OF CHEMICAL INDUSTRY, AGRICULTURE GROUP (at 14 Belgrave Square, London, S.W.1), at 10.30 a.m.—Meeting on "Statistics".

INSTITUTION OF CHEMICAL ENGINEERS, SOUTH EASTERN BRANCH (at the Geological Society, Burlington House, Piccadilly, London, W.1), at 2 p.m.—Symposium on "Hydrogen for Industry".

INSTITUTION OF MECHANICAL ENGINEERS, INDUSTRIAL ADMINISTRATION AND ENGINEERING PRODUCTION GROUP (at 1 Birdcage Walk, Westminster, London, S.W.1), at 6 p.m.—Discussion on "Trends in Machining Techniques and Processes".

ROYAL AERONAUTICAL SOCIETY (joint meeting with the Institution of Electrical Engineers, at Savoy Place, London, W.C.2), at 6 p.m.—Discussion meeting on "The Problem of Aerial Installation and Siting in Modern Aircraft" opened by Mr. R. A. Burberry and Mr. H. Hill.

SOCIETY OF CHEMICAL INDUSTRY, PLASTICS AND POLYMER GROUP (jointly with the Paper and Textile Chemicals Group, at 14 Belgrave Square, London, S.W.1), at 6.30 p.m.—Prof. B. Ranby: "Paper Fibre—Synthetic Polymer Combinations".

OFFICE OF HEALTH ECONOMICS (at the Royal Society of Health, 90 Buckingham Palace Road, London, S.W.1), at 8.30 p.m.—Dr. M. E. Beesley: "Where Does the Public Interest Lie?"

## Tuesday, March 23—Thursday, March 25

ROYAL INSTITUTION OF NAVAL ARCHITECTS (in the Weir Lecture Hall, 10 Upper Belgrave Street, London, S.W.1)—Spring Meeting.

## Wednesday, March 24

PLASTICS INSTITUTE, REINFORCED PLASTICS GROUP (at the Connaught Rooms, Great Queen Street, London, W.C.2), at 9 a.m.—Conference on "Research Projects".

ROYAL SOCIETY OF ARTS (at John Adam Street, Adelphi, London, W.C.2), at 2.30 p.m.—Mr. P. J. Lawther: "Air Pollution and the Public Health".

PHARMACEUTICAL SOCIETY OF GREAT BRITAIN (at the School of Pharmacy, University of London, Brunswick Square, London, W.C.1), at 5.30 p.m.—Prof. Arthur Stoll, F.R.S.: "Ergot—a Treasure House for Drugs" (Hanbury Memorial Lecture).

INSTITUTION OF ELECTRICAL ENGINEERS (joint meeting with the Institutions of Civil and of Mechanical Engineers, at the Institution of Mechanical Engineers, 1 Birdcage Walk, Westminster, London, S.W.1), at 6 p.m.—Mr. J. C. Duckworth: "Incentives to Invention and Innovation" (Eleventh Graham Clark Lecture).

SOCIETY OF CHEMICAL INDUSTRY, OILS AND FATS GROUP AND FOOD GROUP (at 14 Belgrave Square, London, S.W.1), at 6.15 p.m.—Dr. G. D. Rosen: "Food Industrial Developments in Oilseed Proteins and Allied Products".

ROYAL AERONAUTICAL SOCIETY, GRADUATES' AND STUDENTS' SECTION (at 4 Hamilton Place, London, W.1), at 7.30 p.m.—Annual General Meeting and Film Show.

## Thursday, March 25

CHEMICAL SOCIETY AND THE ROYAL INSTITUTE OF CHEMISTRY (at the Middlesex Hospital Medical School, Cleveland Street, London, W.1), at 2 p.m.—Review Symposium on "Organometallic Chemistry".

ROYAL SOCIETY (at Burlington House, Piccadilly, London, W.1), at 4.30 p.m.—Dr. C. R. Burch, F.R.S.: "University Physics—The Challenge of Technology" (Review Lecture).

INSTITUTION OF CIVIL ENGINEERS, TRANSPORTATION ENGINEERING GROUP (at Great George Street, Westminster, London, S.W.1), at 5.30 p.m.—Informal Discussion on "Cargo Containers for All Kinds of Transportation" introduced by Mr. E. S. Tooth.

INSTITUTION OF ELECTRICAL ENGINEERS, SCIENCE AND GENERAL DIVISION (at Savoy Place, London, W.C.2), at 5.30 p.m.—Colloquium on "Critical Path Analysis".

ROYAL INSTITUTE OF CHEMISTRY, LONDON SECTION (joint meeting with the Polytechnic Chemical and Physical Societies, at the Polytechnic, Regent Street, London, W.1), at 6 p.m.—Symposium on "Surface Reactions Using Ultra High Vacuum Techniques".

## Thursday, March 25—Friday, March 26

INSTITUTION OF MECHANICAL ENGINEERS, PROCESS ENGINEERING GROUP (at 1 Birdcage Walk, Westminster, London, S.W.1)—Conference on "Vacuum Technology".

## Friday, March 26

ROYAL AERONAUTICAL SOCIETY, ROTOCRAFT SECTION (at 4 Hamilton Place, London, W.1), at 2.15 p.m.—Mr. G. J. Hunt: "Canadian Autogyro Development"; Mr. N. O. Brantly: "The Brantly Helicopter".

INSTITUTION OF ELECTRICAL ENGINEERS, SCIENCE AND GENERAL DIVISION (at Savoy Place, London, W.C.2), at 5.30 p.m.—Discussion on "Insulating Thin Films".

## Monday, March 29

INSTITUTION OF ELECTRICAL ENGINEERS, SCIENCE AND GENERAL DIVISION (at Savoy Place, London, W.C.2), at 10 a.m., 2.30 p.m. and 5.30 p.m.—Colloquium on "Earth Loop Impedance Testing".

INSTITUTION OF ELECTRICAL ENGINEERS, ELECTRONICS DIVISION (at Savoy Place, London, W.C.2), at 5.30 p.m.—Mr. P. Knight, Mr. R. E. Davies and Dr. R. G. Manton: "Vertical Radiation Patterns of h.f. Curtain Arrays on Plateau Sites".

PLASTICS INSTITUTE, LONDON SECTION REINFORCED PLASTICS SUB-GROUP (at the Eccleston Hotel, London, S.W.1), at 7.30 p.m.—Mr. J. W. Davidson: "Plastics in Building".

ROYAL GEOGRAPHICAL SOCIETY (at 1 Kensington Gore, London, S.W.7), at 8.15 p.m.—Mr. Michael P. Ward: "In Unknown Bhutan".

## APPOINTMENTS VACANT

APPLICATIONS are invited for the following appointments on or before the dates mentioned:

COMPUTING ASSISTANT (with a good honours degree in mathematics or in a pure or applied science, and preferably some experience with large-scale computing machinery) IN THE ELECTRONIC COMPUTING LABORATORY—The Registrar, The University, Leeds, 2 (March 26).

LECTURER (with good academic qualifications and teaching experience) IN EDUCATION with special reference to the teaching of mathematics—The Secretary, University of London Institute of Education, Malet Street, London, W.C.1 (March 27).

LECTURER (well qualified in chemistry and experience in teaching, research or industry) IN INORGANIC CHEMISTRY—The Vice-Principal, Kingston College of Technology, Penrhyn Road, Kingston upon Thames, Surrey (March 29).

CHAIR IN BIOLOGY; CHAIR IN CHEMICAL ENGINEERING; CHAIR IN PHYSICS; CHAIR IN MECHANICAL ENGINEERING; and CHAIR IN PHYSICAL CHEMISTRY—The Secretary, Royal College of Advanced Technology, Salford, 5, Lancashire (March 31).

D.S.I.R. RESEARCH ASSISTANT (graduate in geology, interested in palaeozoic stratigraphy and palynology, and preferably some knowledge of botany and chemistry) IN THE DEPARTMENT OF GEOLOGY—Prof. J. H. Taylor, Head of the Geology Department, King's College (University of London), Strand, London, W.C.2 (March 31).

RESEARCH ASSISTANT (graduate in biology or biochemistry) IN THE DEPARTMENT OF IMMUNOLOGY, to assist in a study of the *in vitro* synthesis of antibodies—The Secretary, St. Mary's Hospital Medical School (University of London), Paddington, London, W.2 (March 31).

LECTURERS OR ASSISTANT LECTURERS IN PHILOSOPHY at Queen's College—The Secretary, University of St. Andrews, Queen's College, Dundee (April 2).

READER IN APPLIED MATHEMATICS at Queen Mary College—The Academic Registrar, University of London, Senate House, London, W.C.1 (April 2).

LECTURER IN GEOLOGY—The Registrar, Magee University College, Londonderry, Northern Ireland (April 3).

LECTURER (with qualifications in social psychology) IN EDUCATION—The Registrar, The University, Manchester, 13, quoting Ref. 41/65 (April 3).

SENIOR LECTURERS (2) IN THE DEPARTMENT OF APPLIED MATHEMATICS—The Registrar, The University, Sheffield (April 3).

CHAIR OF CIVIL ENGINEERING SCIENCE—The Registrar and Secretary, University of Durham, Old Shire Hall, Durham (April 5).

RESEARCH ASSISTANT OR SENIOR RESEARCH ASSISTANT (with an honours degree, G.I.L.C. or Dip. Tech., with suitable postgraduate experience or a higher degree) IN THE DEPARTMENT OF CHEMISTRY, for work involving the study of fluorinated heterocyclic compounds—The Registrar, and Secretary, University of Durham, Old Shire Hall, Durham (April 5).

SENIOR LECTURER and a LECTURER IN THE DEPARTMENT OF BACTERIOLOGY—The Secretary, The Welsh National School of Medicine, 34 Newport Road, Cardiff (April 7).

MASTER to teach Physics to university scholarship level—The Warden, St. Edward's School, Oxford (April 9).

HEAD (preferably with a knowledge of the agricultural industry) OF THE APPLIED NUTRITION DEPARTMENT (the work has special reference to determining the nutrient requirements of farm livestock)—The Secretary, The Rowett Research Institute, Bucksburn, Aberdeen (April 10).

LECTURER OR ASSISTANT LECTURER IN MATHEMATICAL STATISTICS, to work with an existing group of five members of staff—The Registrar, The University, Manchester, 13, quoting Ref. 48/65 (April 10).

LECTURER OR ASSISTANT LECTURER (preferably with special interests in applied mathematics) IN MATHEMATICS at Queen's College—The Secretary, University of St. Andrews, Queen's College, Dundee (April 10).

LECTURER (preferably with previous experience in histopathology and morbid anatomy) IN VETERINARY PATHOLOGY at the Royal (Dick) School of Veterinary Studies—The Secretary, University of Edinburgh, Old College, South Bridge, Edinburgh (April 10).

JUNIOR LECTURER IN PSYCHOLOGY, and a JUNIOR LECTURER IN ZOOLOGY—The Secretary, Trinity College (University of Dublin), Dublin, Republic of Ireland (April 12).

LECTURERS (2) IN BOTANY (one in plant physiology, and the other preferably in morphology or taxonomy) at the University College of Rhodesia and Nyasaland—The Secretary, Inter-University Council for Higher Education Overseas, 33 Bedford Place, London, W.C.1 (April 15).

READER IN THEORETICAL PHYSICS, and a LECTURER IN THEORETICAL PHYSICS—The Secretary, Chelsea College of Science and Technology, Manresa Road, London, S.W.3 (April 15).

**LECTURER IN APPLIED MATHEMATICS**—The Reader in Biometry, Unit of Biometry, University of Oxford, 7 Keble Road, Oxford (April 17).

**LECTURER** (with a special interest in the investigation of biochemical problems in plant pathology) in **BOTANY**—The Registrar, The University, Manchester, 13, quoting Ref. 47/65 (April 20).

**RESEARCH FELLOW** (medical graduate with an interest in biochemistry and child nutrition) in the **DEPARTMENT OF BIOCHEMISTRY**, University of Ibadan, Nigeria—The Secretary, Senate Committee on Higher Education Overseas, University of London, Senate House, London, W.C.1 (April 20).

**ASSISTANT LECTURER IN MATHEMATICS**—The Secretary, Chelsea College of Science and Technology, Manresa Road, London, S.W.3 (April 23).

**CHAIR OF EDUCATION** at the University College, Nairobi (University of East Africa)—The Secretary, Inter-University Council for Higher Education Overseas, 33 Bedford Place, London, W.C.1 (April 23).

**READER IN PURE MATHEMATICS**—The Secretary, Chelsea College of Science and Technology, Manresa Road, London, S.W.3 (April 23).

**SENIOR LECTURER IN THE DEPARTMENT OF ORGANIC CHEMISTRY**, University of Western Australia—The Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (Australia and London, April 24).

**LECTURER** (with postgraduate qualifications and research interests in experimental psychology) in **EXPERIMENTAL PSYCHOLOGY**, at the University of Auckland, New Zealand—The Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (New Zealand and London, April 30).

**RESEARCH FELLOWS IN COMPUTING: FLUID DYNAMICS AND HEAT TRANSFER; NUCLEONIC INSTRUMENTATION; REACTOR CONTROL AND KINETICS; AND REACTOR PHYSICS**—The Secretary, Winfrith Fellowship Board, A.E.E., Winfrith, Dorchester, Dorset (April 30).

**LECTURER IN EDUCATION** at the University College, Nairobi (University of East Africa)—The Secretary, Inter-University Council for Higher Education Overseas, 33 Bedford Place, London, W.C.1 (May 23).

**GOLDSMITHS' CHAIR OF METALLURGY**—The Registrar, University Registry, The Old Schools, Cambridge (May 29).

**READER IN MINERAL INDUSTRY** at Imperial College—The Academic Registrar, University of London, Senate House, London, W.C.1 (May 31).

**SENIOR LECTURER OR LECTURER IN TROPICAL MICROBIOLOGY AND IMMUNOLOGY; A SENIOR LECTURER OR LECTURER IN TROPICAL SOCIAL AND PREVENTIVE MEDICINE; and a LECTURER IN TROPICAL MEDICINE** (Technical Assistance Lectureships)—The Secretary, The University, Edinburgh (May 31).

**MASTER** to teach Chemistry throughout the School—The Headmaster, Merchant Taylors' School, Crosby, Lancashire.

**MASTER** to teach Mathematics throughout the School, including the Sixth Form—The Headmaster, Bristol Grammar School, Bristol, 8.

**POST-DOCTORAL INVESTIGATOR** for work with Dr. S. G. Waley on the structural chemistry of lens proteins—Dr. Waley, Nuffield Laboratory of Ophthalmology (University of Oxford), Walton Street, Oxford.

**SENIOR RESEARCH WORKER** (post-doctoral or equivalent) for work sponsored by the Ministry of Defence on the chemical engineering aspects of two-stage oil combustion processes with intermittent heat exchange—R. P. Fraser, O.B.E., Chemical Engineering and Chemical Technology Department, Imperial College, London, S.W.7.

**SENIOR FELLOW IN THE BOTANY DEPARTMENT**, 68 Half Moon Lane, S.E.24, for duties which will include assisting in research and teaching—The Secretary, Ref. 6604, King's College, Strand, London, W.C.2.

# PRECISION ULTRAVIOLET AND VISIBLE SPECTROSCOPY FOR £815

The Unicam SP.500 Ultraviolet and Visible Spectrophotometer is now available complete for mains operation for £815.\*

This well tried and proven instrument is to be found in laboratories throughout the world where its accurate reliable performance has set new standards.

With the Unicam SP.500 there are no extras required for normal operation the price includes everything necessary for precision all mains operation, deuterium lamp supply, 115 D power supply and SP.549 internal power unit—right down to four glass and two silica cells in cases and a set of dust covers. In the U.K. installation is free. All you provide is your sample.

Write for the SP.500 booklet today.

# AGAROSE

A neutral galactose polymer obtained from Agar by a unique method using reagents having no toxicity.

- \* Negligible electroendosmotic properties.
- \* High gel strength.
- \* Non-toxic.
- \* Minimum adsorption properties.

This product and many ENZYMES and RELATED BIOCHEMICALS of the highest possible integrity are produced entirely in our own laboratories.

have been publishing scientific and technical books for nearly 150 years, including those in such typical fields as:

AERONAUTICS, ASTRONOMY, CHEMISTRY, ELECTRONICS and CONTROL ENGINEERING, METALLURGY, PHYSICS, STATISTICS, MATHEMATICS and ECONOMICS. . . .

**PRECISION INSTRUMENTS**

### NEW FEATURES—

This equipment now incorporates automatic Verdet Dispersion Correction and range change switching, water jacketed sample chamber and nitrogen purging of the optical deck.

*For full details and specification, price and delivery, write to Dept. N.*

Manufactured under licence. Patent No. 918078

The electronic unit for this instrument is manufactured by Messrs. Bendix Electronics Ltd., of Nottingham

## *The* **POLARMATIC 62** *Automatic* **Spectropolarimeter**

RANGE—181 to 600 millimicrons.

ROTATION—Up to 1.4 degrees at 200 millimicrons positive or negative.

SAMPLE TUBES—5, 10 and 20 mm standard. Water jacketed types available.

RECORDER—Flat bed plotter.

RECORDING TIME—200 to 600 millimicrons in 20 minutes.

## FOUNDATIONS OF SCIENTIFIC POLICY

THE lecture on science and Government which Dr. S. Toulmin gave in October 1964, and which has now been published in the January and February 1965 issues of *State Service* (the journal of the Institution of Professional Civil Servants), makes particularly interesting reading in the light of subsequent changes in the organization of civil science in Britain and of two recent books. Both Mr. S. Brittan's *The Treasury under the Tories: 1951-1964\**, and Mr. N. H. Brasher's *Studies in British Government†* were written before the change of Government, and Dr. Toulmin's lecture was delivered before the election, but all three gain rather than lose in pertinence through the consequent detachment, and by and large the differences in emphasis and in points of view are suggestive for the scientist. Moreover, Dr. Toulmin does much more than repeat the arguments of his earlier paper printed for private circulation, also *Nature*, 200, 503, 1030; 1963), and if the title "Foundations of Scientific Policy" could be equally appropriate for this lecture, the whole structure of his argument is adapted to the wider and perhaps less-informed audience he addressed in October.

He begins by drawing a three-fold distinction. Science can be, first, the servant of the formation of policy, as when technical advance contributes to decisions regarding defence or the administration of prisons. Secondly, it can itself be the subject of policy, as when the University Grants Committee or the Advisory Council on Scientific Policy advises on the allocation of central funds for the support of scientific research. Thirdly, it can be an instrument in the formation of policy, as when the analytical work of a Buchanan or a Moser contributes to the solution of political problems by elucidating what the actual choices are for those responsible for taking decisions. This last-mentioned distinction is the newest of the three modes of interaction between science and policy, and it was a main concern of Prof. G. A. Miller's Granada Lecture, "Computers, Communication, and Cognition", in October 1964, which likewise has now been published (*The Advancement of Science*, 21, 417; 1965).

Dr. Toulmin points out that traditionally the structure of Government in Britain has been specifically adapted to deal with the first of these roles, both as regards advice and administration. As one consequence, many scientists have come to be prejudiced against becoming involved with Government and administration, whereas in the present situation the second and third roles have become a vital element in public affairs. This is now recognized by all political parties and is emphasized repeatedly in the difficulties experienced in reaching sound decisions in such matters as aircraft and weapons policy, apart from all questions of party policy. Aloofness and prejudice on the part of the scientist and technologist can to-day be a real danger to public welfare.

In analysing this situation, Dr. Toulmin turns first to the question of the structure for advice, stating the problem as follows: "When questions arise about the bearing of science and technology on Government policy,

what sorts of outside advice should Ministers seek, and through what channels?". He answers this question by referring to the way in which, in the past thirty years or so, when the advice of the merchants and bankers in questions of trade, taxation, money and employment proved ineffective the Government turned to the professional economists. Dr. Toulmin suggests that here the formation in 1940 of the Economic and Statistical Section of the War Cabinet Secretariat, which has since developed into the Economic Section of the Treasury, was the crucial step. While he does not claim too much for the intervention of academic economists, he suggests that since 1940 the nations of the West have succeeded, by methods based on the analyses of economic theorists, in avoiding any recession comparable with those which, throughout the previous 75 years, had seemed unavoidable. Moreover, he points out that even the humblest voter is now expected to master some of the basic concepts of economics, and that nobody would now seriously propose to abandon the attempt to base economic decisions on an explicit and thorough analysis of the problems of the day using the best concepts and theories available, and return to relying on unanalysed hunches.

Dr. Toulmin is obviously simplifying, and his suggestions should be considered in the light of the much fuller discussion of economic policy contained in Mr. Brittan's book. Leaving that aspect for the moment, Dr. Toulmin uses the transition in the formation of economic policy to illustrate his main thesis that the corresponding transition has not taken place in the arrangements for obtaining expert advice about the issues of scientific policy. What the Government should seek here in its advisers is something much more than profound knowledge within science proper: rather an understanding of scientific affairs is needed, of that whole complex network of processes by which the activities of scientists and technologists interact with the rest of the national life, and of the economic and political consequences of these interactions. This requires a much deeper study and understanding of the interactions between science and other areas of public concern—a fresh grasp of the social roles of scientific research and technological development, their potential contributions to public affairs, and the problems to which they give rise, comparable with the grasp we have gained from economics of the roles, problems and potentialities of money, trade, industrial production and employment.

While Dr. Toulmin believes that this need is well enough recognized in the international agencies, for example by the Directorate of Scientific Affairs of the Organization for Economic Co-operation and Development, he questions whether scientific affairs have any standing in Britain as a field of serious study. He is critical that the one really promising programme of research on the economics of research and development under Mr. C. Freeman at the National Institute for Economic and Social Research should be financed not from any British source but under contract from the Organization for Economic Co-operation and Development. It is difficult to point to anything in the pattern of recent changes which could offset the frustration which Dr. Toulmin himself has experienced or remove the obstacles he describes. The essential

\* *The Treasury under the Tories, 1951-1964*. By Samuel Brittan. (Pelican Book A 722.) Pp. 375. (London: Penguin Books, Ltd., 1964.) 6s.

† *Studies in British Government*. By N. H. Brasher. Pp. vii + 177. (London: Macmillan and Co., Ltd.; New York: St. Martin's Press, Inc., 1965.) 18s. net.

studies on scientific affairs, he believes, are being frustrated by the continued dominance within the administration of men whose training excludes all first-hand knowledge of scientific subjects. Further, this situation is maintained by the basic structure of the Civil Service and the pattern of the educational system feeding it.

In arriving at the question of the mechanism of administration, Dr. Toulmin reaches a conclusion that Sir Henry Tizard arrived at long ago: we must recruit our future administrators of the first rank from young men and women who are at ease with science and scientific affairs, and the universities must shape their curricula to permit such an education, combining, for example, the analytical training of the Greats course, with an emphasis on cogency, literacy and intellectual discrimination, with a general grasp both of scientific ideas and of scientific affairs. An administrator to-day has inescapably to experiment and innovate in every field of public affairs and, for sound judgment, discrimination, balance and knowledge, particularly new knowledge, must be added. In all its branches Government will be forced increasingly to sponsor and apply the results of deliberate social research.

Anomalies, such as Dr. Toulmin notes in this lecture, do not appear to have been removed in the new structure set up by the present Government, nor does it appear that the barriers and salary-differentiates between the higher administrative grades and the professional grades have as yet been dismantled as Dr. Toulmin suggests. Beyond all this, however, one further essential step has to be taken: the creation of a central 'research and intelligence' section to serve the Ministries responsible for science policy, having a status comparable with that of the Economic Section of the Treasury. Such a section would also undertake *ad hoc* enquiries about scientific manpower, priorities and economics. Moreover, it would have the right and the duty to sponsor parallel enquiries in universities and other outside organizations, with the view of promoting long-term thought about the problems of scientific policy. In so doing, it would foster the informed public opinion necessary for the intelligent discussion of the politics of science.

It is for its contribution to the understanding of the working of the British Government at the present time and more particularly for the light it throws on the threats to traditional freedoms latent in present concepts of Government that Mr. Brasher's *Studies in British Government* is of interest to the scientist and technologist. Mr. Brasher's title is not well chosen, for although it is intended to stimulate discussion it lacks the depth that such a title would suggest. While it ranges more widely than either Mr. Brittan's *The Treasury under the Tories* or Mr. B. Crick's *The Reform of Parliament*, it is too penetrating to be fairly described as discursive. Mr. Brasher gives readable accounts of the place and functions of the Monarchy, the Cabinet and the Prime Minister, and Ministers and Civil Servants. He interpolates a chapter on the redress of grievances before proceeding to discuss, successively, the House of Commons and its procedural problems, the implications of different electoral systems, the House of Lords and some problems in the administration of justice. Before finally attempting to assess the present strength and weakness of the British constitution he glances briefly at some recent and prospective changes in local government and at Britain's relations with the Commonwealth, more especially at the problems presented in granting independence.

On the powers of the Prime Minister and the Cabinet as against the House of Commons, Mr. Brasher is as penetrating as Mr. Crick if somewhat less forthright. While he believes that, so far as the Civil Service is concerned, the doctrine of Ministerial responsibility give reasonable safeguards for the ordinary citizen, he considers that new forms of protection are required for the freedom of the citizen since the traditional safeguards are losing their effectiveness. He sees in the House of Lords one means by which more time could be secured for the Commons to consider the increased volume of legislation but when it comes to the problem of how to secure stronger Parliamentary control over matters which specialization to-day has made intelligible only to the expert, he never mentions the question of scientific and technological advice. He is rightly critical of the way in which time is wasted in the House of Commons by all parties, but on this central issue in the relation of science and technology to public policy he gives no further hint that its existence is recognized.

Mr. Brasher disclaims, it is true, any suggestion that his book is comprehensive, and in the context of this question of science and Government it should be noted that most of the book was written in 1962, well before both political Parties gave the issue its present prominence. None the less, it is perhaps significant that substantially the same criticism could be made against Mr. Brittan's book for all its concern with the mechanism and effectiveness of advice in economic and financial matters. Admirably as Mr. Brasher has set forth certain trends, such as the growth of central direction and the nature of the ultimate restraints on Government authority it is vital that this omission should be remembered and its implications receive due consideration.

Much of the first part of Mr. Brittan's book complements or duplicates Lord Bridges's recent book on *The Treasury* (Nature, 203, 555; 1964), but the second part on "Economic Steering" is highly relevant to the relations between the Treasury and the Ministry of Economic Affairs established by the new Government, and to any stress or strain that may develop between these two Departments, and even between them and others such as the Board of Trade or the Ministry of Technology. Added to this, Mr. Brittan is now one of Mr. G. Brown's expert advisers in the Ministry of Economic Affairs for which his book argues. Mr. Brittan holds that, at least so far as economic policy is concerned, the traditional relation between Ministers and Civil Servants has broken down under the sheer complexity of the issues. The Civil Service is not a ruling bureaucracy and the system can only work successfully if the guiding lines of policy come from the Ministers themselves. Mr. Brittan does not appear to favour the practice of asking distinguished outsiders to pronounce on essentially political issues: on the contrary, he challenges the whole idea of impartial advisers analysing 'means' and politicians choosing 'ends', and suggests the creation of a new class of adviser, distinct from the main Civil Service, with both political and technical responsibilities.

These advisers would be selected in accordance with the personal preferences of Ministers and would move freely in or out of the academic world, industry and the professions, tending to change with Governments but not necessarily so. The system would, above all, be flexible and take account of the fact that many of the real divisions of opinion and of personal compatibility cut across Party lines. These advisers differ appreciably from those which Lord Bridges rejected as undesirable in a

broadcast talk last June: it is possible that they are similar to what the present Prime Minister has in mind. Nor does Mr. Brittan think that such a scheme would adversely affect recruitment to the permanent Civil Service: it is a bad and not a good feature of the present system that high officials should be able to opt out to the present extent from the political consequences of their advice. Furthermore, he visualizes some administrative advantages in the scheme as well as a decisive encouragement to mobility and interchange between the Civil Service, private or nationalized industry, the universities and the professional world generally.

Mr. Brittan is careful not to claim too much for the greater use of professional experts in this way. Undoubtedly the process could itself help to promote informed criticism and, as he remarks, the quality of advice might well be improved if officials were more often required to defend it in public against expert criticism: there is no reason why a democracy should acquiesce in conventions designed to save the Government any embarrassment in all circumstances. Such criticism and the public explanation of Whitehall thinking would be assisted by establishment of the specialized House of Commons committees which have often been advocated, and by providing better working conditions for Members of Parliament. In the last resort, however, no weaknesses in either the Civil Service or the House of Commons can excuse the Government from its own responsibilities.

Mr. Brittan, no more than Dr. Toulmin, suggests that institutional arrangements can be a substitute for right decisions on policy. They may increase the chances of a right decision, and his concluding chapter on the choice of priorities is particularly pertinent in relation to the changes which have now been made with regard to the National Economic Development Council. The real significance of establishing that Council, he suggests, was that it was a potential pressure group for growth, and this should apply to any new Ministry that takes over its function. Such a planning organization does not need powers to ensure that its forecasts are fulfilled. Its value lies in spotlighting the need for regional policy, for training and redundancy schemes, tax reforms and numerous ways of improving efficiency as well as in putting forward ideas for policy, and especially in ensuring that Government policy is held firm to ensure the achievement of that target of growth to which the Government has committed itself.

Mr. Brittan suggests that the confidence with which both sides of industry have treated the National Economic Development Council is due largely to their belief that it is their own organization and not a Government Department—an advantage that cannot be overstressed. Nor does he favour the establishment of a new Economic Ministry to determine strategy, leaving the Treasury to determine tactics. He would start with the existing Treasury as a base, but transfer control of Government expenditure to a separate Expenditure Bureau. If the control of the Civil Service went to an enlarged Civil Service Commission the Treasury would be rid of some of the main psychological impediments to its acting as a proper Economics Ministry and could become specifically responsible for advising on spending projects conducive to growth. The residue could also enlarge its functions, take a more detailed interest in industry and hold a wide brief to think about economic policy as a whole.

Mr. Brittan's proposals obviously differ considerably—and suggestively—from the new structure which has

emerged with the establishment of a Ministry for Economic Affairs, even if the details are as yet by no means clear. The alternative centre of power which he desiderates now exists, and it remains to be seen whether the influence of the Bank of England or traditional preoccupation with candle-ends continues to hinder economic growth. Beyond this, however, there are even wider issues on which his book throws some light, and if, regrettably, he himself does not touch on this question of science and Government and the structure or character of scientific advice for those alive to such issues his book is scarcely less suggestive than Dr. Toulmin's lecture.

## LANGUAGE OF THE SOCIAL SCIENCES

### A Dictionary of the Social Sciences

Edited by Julius Gould and William L. Kolb. (Compiled under the auspices of the United Nations Educational, Scientific, and Cultural Organization.) Pp. xvi+761. (London: Tavistock Publications (1959), Ltd., 1964.) 136s. 6d. net.

THE publication of *A Dictionary of the Social Sciences* represents the achievement of a great success for the Department of Social Sciences of Unesco. The object of its compilers has been to present "a general introduction to the main problems and developments" in the social sciences, and "to provide for specialists in other disciplines a source of understanding of the main concepts used in fields outside their own". This undertaking is a formidable one, because the social sciences are still far from sharing a common outlook, methodology, or even language. The barriers that separate sociology from political science and economics still remain more or less apart. But there is a tendency for sociology, anthropology, and (in some degree) psychology to come together on a common front, and there is evidence in the *Dictionary* that a certain mutual interest is developing. The effort that has gone into its compilation cannot but stimulate its further development.

It is a remarkable thing, then, that the *Dictionary* has been compiled at all. It is much more remarkable that the results are so impressive, and that the difficulties mentioned here have been overcome so satisfactorily. It achieves both its special and its general purposes outstandingly well. It is a genuine 'must' to all practising social scientists, who should all have access to it, and the nearer they have it within reach, the better for them. In general, the authors have proved themselves to be well informed, conscientious, and fair-minded, even when they tackle the more awkward aspects of highly controversial subjects. Moreover, their writing is usually clear and precise, which is not true of the common run of social science texts.

So far as content is concerned, the articles by Americans outnumber those by British Commonwealth authors by two to one. As might be expected, this creates a certain bias towards American ways of looking at things in the social sciences, but this is nothing like so serious or as intellectually misleading as the fact itself would lead one to expect. Bias is sometimes apparent, as in the articles on race and racism, but the fault is one of proportion and balance rather than in fundamental approach or method. Furthermore, there is the problem that is general in the social sciences of the significance of what an American author has called "intendedly rational behavior" as a subject of study, for social scientists "have come to be suspicious" of the assumption that social behaviour can be regarded by them as autonomous and purposeful. Social scientists are much more at their ease when they deal with the influences of social environment than when

they seek to examine individual choice and intention, or processes of planning and administration. It is to be regretted that there is no article on, for example, so-called applied sociology, which might have dealt with what is so often termed 'problem-centred' work. There is, however, one on applied anthropology by Dr. Margaret Mead, in which the issue is briefly mentioned, but the articles on welfare and social problems do not go to the root of the matter.

These are no more than blemishes, however, and are fully redeemed by the value of the work as a whole for general use. Some words, such as 'anomy', may be understandable as terms of art by the social scientist; they involve esoteric mysteries to the uninitiated. Their use is becoming more common as they refer to universal problems in the modern world, and clarification of their meaning is thus welcome. Others, such as 'value', have both general and special meanings. In so far as they may have a limited, but not at all precise, significance when used in connexion with sociological theory, they again require clarification with some degree of urgency. Finally, many new words, such as 'scientism' or 'meta-sociology' (the latter dealt with in the *Dictionary* under the umbrella of that inelegant word 'metaanthropological'), are coming into common circulation, and the social scientist finds himself having to do too much explaining about their uses. Here, again, the publication of the *Dictionary* is helpful, as a labour-saving device.

T. S. SIMEY

## QUID HOC NOMEN GENERICUM ORCHIDEUM SIBI VULT?

### Generic Names of Orchids

Their Origin and Meaning. By Richard Evans Schultes and Arthur Stanley Pease. Pp. xiii+331. (New York and London: Academic Press, 1963.) 86s.

THE Latin names of plants, until the middle of the eighteenth century, were usually brief phrases which described the plant. From 1753 onwards the binominal system of Linnaeus has been increasingly used and to-day there is an international code of nomenclature governing the formation and application of these binominals, which may refer to a feature of the plant or to its habitat or locality or may commemorate its founder or a famous person. The majority of early botanists were classical scholars well versed in ancient Greek or Latin and to-day a certain number of mainly older workers have a wide knowledge of these languages. To most of us, however, Latin, if we learnt it at all, probably ended in the fifth form and consequently the wealth of information contained in the Latin names of organisms remains untapped.

The orchids, because of their combination of peculiar botanical, horticultural and aesthetic qualities, have always aroused a special interest in botanists, gardeners and flower lovers. This interest, plus the fact that the orchids comprise the largest family of flowering plants, obviously suggested to two Harvard scholars that an etymological dictionary of orchid generic names would be an essential as well as a fascinating book to taxonomists and non-taxonomists alike.

Thus a taxonomic botanist, Dr. Schultes, and a classical scholar, Prof. Pease, joined forces to produce *Generic Names of Orchids: Their Origin and Meaning*, which alphabetically lists some 1,250 names. In addition to their etymology, the place of first publication of each genus is given together with a summary of its geographical distribution and its position in the standard work on the classification of the family. Genera with interesting and unusual features are illustrated by excellent line drawings of one or more of their species. Some of these are rather fanciful but serve well to illustrate their point.

Others, for example those showing orchids in cathedral settings, are perhaps a little out of keeping in a scientific text-book. However, this emphasizes the fact that systematic botany, a complete appreciation of which necessitates knowledge of modern taxonomic methods as well as of literature up to more than two hundred years old, is not so narrowly specialized as many other scientific disciplines.

For those who have little knowledge of the orchids Dr. Schultes has added excellent introductory sections on the Orchidaceae, their morphological features and economic uses together with a summary of their classification, which is basically that of Schlechter. For those who are not taxonomists, there are introductory articles on vernacular and taxonomical nomenclature and an account of the International Code which governs the latter.

It is unfortunate that the work is incomplete in that many genera are not mentioned, inaccurate in that there are rather too many obvious typographical errors, and incorrect in the stated and supposed meaning and origin of several of the generic names. For example, *Baskerville* is not in honour of the engraver John Baskerville, but is almost certainly dedicated to the young student and great friend of Prof. Lindley, Thomas Baskerville, who died at an early age. *Osyricera* surely has no direct relationship with the Egyptian god of the underworld as stated by Schultes and Pease but was almost certainly likened by its author, Blume, to *Osyris*, a genus of the Santalaceae which was well known at the time the orchid genus was described.

However much these rather too numerous errors of fact and omission may offend and distract the working botanist, the reader must realize the enormous amount of work that has gone into the preparation of this book and the authors must be congratulated on conceiving and producing such a useful and fascinating volume. It must be remembered that most of the information contained therein is not to be found in any other scientific publication and it is a good example of a work in which the art of compilation has been successfully combined with genuine research and scholarship.

P. FRANCIS HUNT

## MORPHOLOGY OF INFLORESCENCES

### Die Infloreszenzen

Typologie und Stellung im Aufbau des Vegetationskörpers. Erster Band. Von Dr. Wilhelm Troll. Pp. xvi+615. (Jena: Gustav Fischer Verlag, 1964.) 112.50 D.M. 192s. 8d.

MORPHOLOGISTS concerned with reproductive structures of higher plants have usually directed more attention to flowers than to the axes that bear them. Nevertheless, the inflorescence deserves study as a whole. As a branch system it is often clearly related, but with subtle variations in the distribution of growth, to that of the vegetative phase from which it arises. Functionally, the order of its development and the interrelation of its parts often contribute substantially, by determining the spatial and temporal pattern of the opening of the flowers, to the effectiveness of the reproductive phase. Dr. Troll believes, with justice, that this neglect of the study of the inflorescence follows from two related deficiencies; first of a satisfactory natural system of classification of inflorescences, and second of a philosophical framework enabling the investigator to reduce to manageable proportions the multiplicity of detail involved.

Troll's approach to the morphology of inflorescences is that of an unrepentant, indeed enthusiastic, typologist. This will come strange to many contemporary botanists for whom 'type' and 'typology' have become almost improper words. This undoubtedly reflects failings in

the teaching of morphology, because typology, used with understanding, is a very effective method of organizing information, and facilitating discussion and comparison of complex biological material. This first volume of what is to be a four-volume treatise does in fact go far to vindicate, by the clarity of the reasoning and presentation, the author's philosophical position.

Two of the nine sections promised are contained in *Die Infloreszenzen: Typologie und Stellung im Aufbau des Vegetationskörpers*. The first, devoted to a general account of flower-bearing systems, introduces a scheme of classification based largely on Eichler. Simple inflorescences, in which the branching consists entirely of the production of lateral flowers, are distinguished from complex, in which partial inflorescences stand in the place of the flowers of simple inflorescences. Dr. Troll maintains that the ground plan of all inflorescences is monopodial, and on this reasoning the cyme cannot be accepted as a simple inflorescence, but as a complex derived (conceptually) from the thyrsus by suppression. The section concludes with a discussion of the various forms of fusion and unequal growth which so modify the appearance of many inflorescences. The second section, which initiates the typology of inflorescences, begins with a series of rigorous definitions. The compound inflorescence becomes technically a *Synfloreszenz*, terminating in a *Hauptfloreszenz*, and bearing below *Paracladien*, each terminating in a *Cofloreszenz*. The remainder (some two-thirds) of the book consists of illustrations of the concepts defined, the species concerned representing a wide, but largely herbaceous, range of higher plants.

*Die Infloreszenzen* is certainly outstanding. It has all the care and penetrating observation that have distinguished Dr. Troll's earlier work, and, within the framework chosen, it is intellectually stimulating and of enviable scholarship. There are abundant drawings and many photographs of a remarkably high standard, on which the artists and printers should also be congratulated. Provided they are interested at all in the growth of higher plants, botanists generally, even those of an entirely empirical temperament, will find an acquaintance with *Die Infloreszenzen* a rewarding experience. P. R. BELL

## ELECTRONICS: ADVANCES AND EXPANSION

**Advances in Electronics and Electron Physics**  
Vol. 18. Edited by L. Marton. Pp. x+342. (New York and London: Academic Press, 1963.) 89s. 6d.; 12.50 dollars.

NO detailed definition of 'electronics' would survive long enough to be of more than historical value, and any attempt to set a limit to the subject's coverage would meet much disapproval. But a measure of the price one must pay for a carefree approach to the question "What is electronics?" is given in this volume of the series of reviews of progress made in electronics and electron physics. Five subjects are surveyed, spread over a very wide field; one of them is indisputably electron physics and a second almost emphatically so even though it is largely applications of known principles to new instrumentation. A third subject is electronics as many users of electronic devices understand it. By contrast a fourth might have appeared equally well under other omnibus headings, such as spectroscopy, or the Earth's atmosphere; electron physics has to stretch itself somewhat to encompass it. The fifth, on computer organization, has negligible electronics content to warrant inclusion. Such wide coverage may discourage sale other than to libraries, or may call for publication of the articles separately.

The first article, on the nightglow, is short and is largely a collection of observations. The spectral line due

to atomic oxygen at 5577 Å figures prominently; much speculation persists concerning the conditions applying in the regions of the Earth's atmosphere where the emission originates. The next, and even shorter, article is on computer logical organization. The cost of using modern digital computers has been as much reduced by attention to programming as to design principles and reliability. Among the improvements discussed and illustrated here are time-sharing and real-time multiprogramming, content-addressed memories, multi-level memories and the fixed-plus-variable structures which afford added flexibility.

A longer article then looks at a subject with much history—collisions of low-energy electrons and ions with atoms and molecules. It remains of great interest because of the intrinsic simplicity of the systems being studied. The new data provided by refining old experimental techniques and introducing new methods, such as using the microwave conductivity of a discharge, have made necessary reassessment of the relative importance of the processes responsible for the transfer of energy and charge.

A second long article examines how far the electrical performance of junction transistors and diodes conforms to expectations based on the structures and the physical theories of the effects at work. The objective is very worthy but the author fails at times to prevent the diversity of effects from confusing his approach. Direct current and transient properties receive most attention. Despite several references to work published since 1960, the review reflects much more nearly the position in the late 'fifties.

The final review is of electron emission microscopy, a subject which has received much attention in Europe. It shows promise of competing with or complementing transmission microscopy, though the best resolution obtained so far is only of the order of 100 Å. The three main methods described use photo-emission by ultra-violet irradiation, secondary emission by electron bombardment and secondary emission by ion bombardment. With the second method, the primary beam can scan the specimen, and the intensity of the secondary electrons produced can be synchronously presented on a television tube for easy viewing and photography.

J. R. TILLMAN

## BONE AND TOOTH SCIENCE

### Bone and Tooth

Edited by H. J. J. Blackwood. (Proceedings of the First Symposium held at Somerville College, Oxford, April 1963.) Pp. xvii+425. (London and New York: Pergamon Press, 1964.) 100s. net.

THE first European Bone and Tooth Symposium was held in Oxford in April 1963. The title of this book and of the Symposium derives from the Bone and Tooth Society, formed in London in 1950 to bring together all those involved in research provoked by an interest in bones, teeth and calcium metabolism.

Many countries and disciplines were represented at the Symposium. As a live pulsating thing it was adjudged a success: this book forms the permanent trace of its existence. Forty short papers and four longer lectures were read. Three of the lectures are now presented in brief summary form. For one of the short papers, only an abstract was available in time for publication. All the contributions are presented in English and there are useful references at the end of most papers. A bibliographical index is included at the end of the book. Since many of the contributors vanished to the four corners of Europe and beyond within minutes of the end of the Symposium, and since a certain amount of opposition to publication of the proceedings was democratically expressed during

the Symposium, the editor's task was clearly not an easy one. It has been well and carefully done.

Since the formation of the Bone and Tooth Society in 1950, a variety of research tools has provided a wealth of data for analysis and digestion. Microradiography, electron microscopy, histochemistry, bone biopsy, tetracycline labelling, radio-isotope tracer studies, not to mention spectacular advances in biochemistry have revolutionized thinking about the dynamic behaviour of bone. For the treatment of patients with bone diseases, a much better model of bone behaviour is now available. These techniques and some of the advances they have produced are well represented in this Symposium, at which the balance between experimental and purely laboratory work on one hand, and clinical and closely allied investigations on the other, seems to have been a reasonable one.

There is a group of four papers related to the use of tetracycline as a marker. There are two papers devoted primarily to studies of bone turnover using microradiographic techniques. There are two papers on the role of the adrenals in the control of calcium-levels in plasma, one paper on hypercalcaemia associated with carcinoma of the breast and a prescient article on calcitonin, based on a consideration of Copp's work, of control systems in general, and of experimental evidence relating magnesium and parathormone.

The interest in kinetic studies is reflected in the considerable number of papers in which calcium or strontium isotopes were the fundamental tools. The hazards of nuclear fission and fusion and terrestrial contamination have brought as a useful by-product a great deal of fundamental work on bone-seeking isotopes with studies on their location in bones and teeth.

A vastly increased interest in bone matrix and its components is manifest in this Symposium, and no fewer than nine papers can be said to be related to this topic. By contrast, fewer than half this number of papers is concerned with inorganic and physical chemical investigations of bone mineral and related compounds.

Two clinical papers are devoted specifically to studies in human osteoporosis. There is a very detailed and precisely documented account of 42 cases of idiopathic osteoporosis in men younger than fifty-five years, with comments on treatment by oestrogens and calcium supplements. The other paper is concerned with the effect of calcium supplements on the spinal density of patients with osteoporosis, the spinal density being estimated by a densitometric analysis of lateral tomograms of the lumbar spine and intervertebral disks.

There are single papers on many other topics—organ culture, enzymes of cells in bone, the structure of dental enamel, the tensile strength of human compact bone, parallel chemical and microradiographic studies of osteoporotic, osteomalacic and normal human bone, a palaeontologist's account of the origin of bone, etc.

This Symposium offers a useful selection of the contributions of European workers to the advancement of knowledge of living bone up to April 1963.

F. H. DOYLE

## A PROBLEM OF AGE

### Ageing

*The Biology of Senescence.* By Dr. Alex Comfort. Revised and re-set edition. Pp. xvi+365. (London: Routledge and Kegan Paul, Ltd., 1964.) 42s. net.

TEN to fifteen years ago, Dr. Korenchevsky, who may be regarded as the father of gerontology as an organized, internationally recognized research discipline, often recalled the fact that his early years in ageing research had not been easy. Often he came up against official criticism of his plans for studying the processes of ageing. The young research worker intending to embark on a

career aimed at the study of the diseases of the elderly or the processes which bring about changes in ageing organisms, will not to-day be met by such lack of interest. Gerontology has become a scientifically and socially acceptable subject. In Britain the universal interest in the 'ageing problem' has been exemplified by the numerous popular articles and radio and television programmes which, over the past few years, have brought the layman into contact with the research worker. One of the foremost exponents of this popularization of gerontology has been Dr. Alex Comfort, but proof, if such is needed, that the scientific knowledge on which the popular story is based has also been developing apace can be obtained from the fact that Dr. Comfort's earlier book *The Biology of Senescence* has had to be republished in a completely revised form within eight years.

It is not fair to judge new editions of books solely on the basis of statistics, but in a relatively new field it is comforting for practitioners to be able to point to the advancement of their subject by a more than 40 per cent increase in the size of the new edition.

During the past ten or eleven years Dr. Comfort has been in the forefront of one particular aspect of ageing research, namely, the application of analytical procedures to the study of a variety of parameters which alter with age. His work has, in the main, been concerned with non-human populations, and it is not surprising that the bulk of the material presented represents an assessment of his own findings in the light of the observations of other workers throughout the world. Although this preoccupation with survival tables is understandable, it might give a rather lop-sided view of the progress of gerontology over the past decade to any newcomer to the field who treated the sub-title of the book in its broadest sense and looked for a fuller coverage of the work of those groups which have been considering biological changes in ageing in the present-day fashion at a molecular level.

Although this type of approach is mentioned in passing the references are more in the nature of an annotated bibliography than a true review of the situation, and it is significant that such references appear, in the main, in the introductory chapters.

One interesting inclusion in the new edition is a chapter on the effect of ionizing radiations. Here the reader is introduced to the beginnings of what will obviously provide a basis for much future work, but its inclusion does demonstrate one of the marked changes which have occurred in the approach to ageing since the first edition was published.

To many readers the section of the book which immediately attracts attention is the chapter on the mechanism of senescence, if only because the theoretical background to a subject always excites most interest. It is therefore a little discouraging that only one new sub-section has been introduced in the new edition. This apparent dearth of new ideas is not, however, so pronounced as would appear from the retention of the old headings. New material on the concepts of somatic mutation, cellular turnover and death, and hormonal control of ageing are discussed at some length, but again the possibilities of the prime lesion being at a molecular level are dismissed in a page.

Ageing can be studied at a variety of levels, dealing respectively with populations, the intact organism, the hormones, the cell, the gene, the enzyme and the molecule. Dr. Comfort's book deals in the main with the first half of this list, but although workers in other fields may regret the lack of coverage of the latter half, the excellence of the author's presentation does much to justify his more limited approach and should act as a stimulus to other writers to provide a review of the relevant material. Gerontology, or geratology as Dr. Comfort would like to see it called, has come of age. No longer can one author do it justice.

D. A. HALL

## SCIENCE AND ENGINEERING

In his inaugural address as president of the Institution of Electrical Engineers, on October 8, 1964, Mr. O. W. Humphreys spoke from long experience of industrial research and organization.

Describing electrical engineering as a science-based industry, Mr. Humphreys observed that the early power engineers, with little but basic scientific principles to guide them and exploiting their own inventive genius, were not infrequently ahead of scientific investigation. In electronic engineering, however, scientific and technological development had from the beginning gone hand in hand and now throughout the whole field interdependence was complete.

Research could, very broadly, be divided into that designed to be, either directly or indirectly, of benefit to industry and that concerned with the study of environment from which no return, other than that of deeper understanding, is demanded. This fundamental research increasingly required the use of very costly tools, and a country's capacity for advancing this type of knowledge may well depend as much on financial resources as on the skill of its scientists. Fundamental research is international and its results are, in the main, freely published.

Research of importance to industry may again be subdivided into 'background' research, designed to increase the general pool of knowledge, and 'project' research, which supports a specific development programme. Background research is usually published and thus made available to industry at large, while project research, necessarily closely integrated with development, may well be withheld from publication.

Background research is carried on in universities, in Government laboratories and in industry, and is subject to relatively little co-ordination. Leaving for a moment the special considerations which apply to research associations and accepting that, for this type of research, central planning is impracticable, the fact remains that lack of co-ordination results in a substantial loss of industrially useful output. Each industrial organization determines its research programme very carefully in relation to its own needs, but there is undoubtedly far more overlapping of the areas of activity of different companies with common technological interests than would be dictated by sound considerations of commercial security.

Collaboration in research involves, so far as considerations of national and commercial security permit, exchanges of information as to what is being done or planned elsewhere, knowledge of the broad trends of industrial development and of the nature of the information which industry requires. There is no easy means of devising machinery to serve these purposes, but fairly recently the electronics industry has made some progress in the matter. Eight trade associations, five concerned with electronic equipment, the other three with electronic components, jointly formed an organization, termed the 'Conference of the Electronic Industry', for the purpose of dealing with matters of common interest and concern to the branches of industry represented. One of those interests being research, the Conference gave immediate support to the drive for the creation of a National Electronics Research Council. This Council, incorporated in July 1964, has on its General Committee representatives of the Ministries of Aviation, Defence, Education and Science, the Board of Trade, the Post Office, the universities and the electronics industry. Twelve of the industry's representatives are nominated by the Confer-

ence. The Institution of Electrical Engineers is linked through its Research Committee with the Council's activities. The expressed intention of the Council is to endeavour in the first instance to increase the yield of the existing electronics research effort.

Research associations developed following the establishment of the Department of Scientific and Industrial Research in 1915. There are, to-day, fifty research associations with a total annual expenditure of some £9,500,000, of which in 1963 £7,400,000 came from industry and £2,100,000 from the Government. The Department of Scientific and Industrial Research, in fostering the growth of research associations, expressed its aim as that of developing within industry an appreciation of the benefits to be derived from scientific research. In trying to form some assessment of the effectiveness of research associations it is necessary to recognize that they are varied, not only in their specializations but also in the type of industry which they serve and the kinds of service which they provide. They can, in fact, be divided into four groups. First, there are those serving industries which are still mainly craft based, such as the Baking, Cutlery, File and Furniture Associations. Such associations can be a great source of strength to industries which formerly were almost wholly dependent on the individual skill of their workers and the experience of their management. They are, in some instances, handicapped by their small size. The Iron and Steel and the Ship Research Associations are at the other end of the scale, serving, as they do, very compact industries closely knit in their scientific interests and keenly aware of the vital part which research has to play. These are large associations and their members entrust to them a very substantial part of their research effort.

Another group is typified by the Welding and Production Engineering Research Associations. These associations deal with technologies having, in one form or another, almost universal application in the engineering industry. Their special knowledge and skills are of such a character as would be difficult for an individual company, even a very large one, to acquire. The fourth is a numerically small group of associations which serve scientifically based but rather diversified industries. Of these the Electrical Research Association is a notable example. The electrical industry has among its members some of great scientific strength, whose research resources considerably exceed those of the Association, but, at the other end of the scale, there are small companies which, individually, may show little or no research activity. This presents the problem of reconciling the needs of the scientifically weak and of the scientifically strong members.

The large companies, scientifically strong, are sensible of the advantages of collaboration but find it difficult to decide what form of collaboration is appropriate and the extent to which they can entrust work which is of common interest to outside bodies. Project research, being allied to development, is not usually amenable to collaboration. To an increasing extent background research is becoming more akin to project research. For example, research on semiconductors and development of new manufacturing processes may be carried out by closely integrated research and development teams working in the same laboratory. Work of this kind must be carried out in industry. Notwithstanding these difficulties there is still much research which can be entrusted by a group of manufacturers to a competent research organization. An excellent example of this is the employment, a few years ago, of one of the well-known sponsored research organ-

izations in the United States, by a group of the largest semiconductor manufacturers, to search for new semiconducting materials.

The real need of the scientifically strong companies is for a highly efficient sponsored research organization operated co-operatively by industry and capable of carrying out specified researches which would be paid for by the group of members requiring the investigations. If the sponsors of such research were willing that the results should be published, the Department of Scientific and Industrial Research would contribute to the cost, as the information would be available to industry at large. There has been a growing tendency for industry to share joint programmes among their own research laboratories, and the Department of Scientific and Industrial Research has been devising means whereby this form of collaboration can be encouraged.

Turning from research to engineering development and design, Mr. Humphreys said that three of the main causes of loss of efficiency in the use of engineering and design effort were abortive projects, faulty planning of development and inadequate attention to priorities in design. The biggest single source of wasted effort is, undoubtedly, the abortive project. With a complex project such as the development of a computer, a nuclear power plant or an electronic telephone exchange, where there are alternative technical approaches, it is seldom possible, in the first instance, to say which approach will be the most rewarding. The right course is to proceed by successive elimination, first on the basis of paper studies and then by experimental investigation. Assessments should be made by an independent team, not too directly involved in the studies themselves, and should be made at frequent intervals. When from the process of elimination one technical approach has been selected, assessment must be continued so that changing circumstances can be taken into account and the continuing technical and commercial viability of the project confirmed.

Development is usually related to a marketing date, and whether demanded by the marketing date or not, it is desirable that development and engineering should be compressed into as short a time as practicable. This not only saves cost in itself but also allows the incorporation of the latest design improvements available. However complex a project may be, it can always be broken down into a number, possibly many thousands, of operations to each of which a time can be assigned. There will be a sequence of identifiable stages within which many of

these operations can be performed in parallel. The identification of the sequence of operations which determines the minimum time within which the whole project can be completed—the 'critical path'—is a highly skilled professional operation. Such analysis demands the attention of a team of highly specialized engineers fully backed by computer facilities.

Design is, as a rule, something of a compromise among considerations of performance, reliability, appearance and cost. The ever-present important factor of cost has to be taken into account along with the other parameters which in different projects will have different priorities. In the television and motor-car industries, for example cost is paramount, whereas in the design of a nuclear power station or a telephone exchange, performance and reliability are dominant factors.

Minimum cost or maximum value for money is a study which must be made by a special team of engineers who will study every detail of design with the view of pointing out redundancies which could be eliminated. These engineers should have no responsibilities for anything but cost. This procedure, commonly known as 'value engineering', does call for some measure of special training. These techniques, possessing something of the qualities of 'applied common sense', are finding wider acceptance in industry and can influence substantially the efficiency of utilization of engineering effort.

Mr. Humphreys's review was completed by observations on two further problems of very general interest—the 'information explosion' and education in relation to career prospects in research and engineering management. In regard to the problem of information retrieval he observed: "Difficult though it may be for many of us to understand, the probability that computers may soon be used to analyse, store, select and deliver information demanded of them is very real. . . . It is highly probable that, within the life-time of many of us here to-night, the preparation of literature surveys will no longer require the laborious and very time-consuming searching of the abstract journals, followed by the reading of many papers of which but a few prove to be important. Instead, the research worker will present a description of the information he requires to a computer in language which it can understand, and will forthwith be presented with a list of the papers he should study. In all probability the computer will be maintained and its store of information kept up to date at an information centre connected by permanent data links to its more frequent users".

J. GREIG

## SIGNIFICANCE OF MAJOR MOORLAND FIRES

By J. RADLEY

Royal Commission on Historical Monuments (England),  
23 High Petergate, York

IT has been believed for many years that the fires which rage on Britain's moors in dry years have profound effects on those moors. Exactly how frequent, extensive and effective these fires are has never been considered. The extent to which they remove vegetation and the underlying peat has never been analysed. The following article is an examination of one area, which lies to the east of the Derbyshire Derwent, between Penistone and Matlock, in which an attempt is made to assess the number, frequency and extent of fires, and to examine the vegetation and peat in order to establish the extent to which fires totally destroy them, thus contributing to the erosion of the area and changes in the appearance of the landscape.

Since 1920 some of the fires have been very fierce but none has equalled the 1959 fires in extent and effect.

The fires have caused a large-scale retreat of the edge of the blanket of peat and stimulated a tremendous amount of erosion on the burnt moors, particularly since 1959.

It is impossible to know whether all the fires that have occurred in the area have been noted, and so the evidence must be considered incomplete, but sufficient has been revealed to suggest that fires have not been an important feature throughout history.

### The Peat Cover

The peat, of very variable thickness, covers most of the southern Pennine hills and descends in some places as low as 800 ft. O.D. Generally, the peat consists of a series of beds of brown, acidic, partially humified vegetation of varied compaction. The peat is 'sealed' by a

fairly continuous and interwoven mat of vegetation roots. Within the peat, the water-table fluctuates with precipitation; normally it is close to the surface, but occasionally the peat may dry to a depth of 4-5 ft. During these dry periods the peat, which on most moors is less than 6 ft. deep, is preserved from mechanical erosion by the network of roots. Fires appear to be extremely important as a cause of erosion, particularly on the periphery of the peat cover, where, during dry spells when the shrubs on the surface are tinder dry, intense burning may devour the plants and shallower peat and effectively reduce the area of blanket bog.

### The Cause of Fires

One can rarely be sure of the exact cause of any particular fire. Before 1900 fires were linked with pipe-smokers, but opposed to this is the care taken by the moorland's occupants, and the precious nature of the minute quantities of tobacco used in the 'fairy pipes' and other clay pipes. The recording of moor fires by the Press has tended to be more colourful than exact; a cause has always been suggested, often without any supporting evidence.

Tobacco from pipes and home-made cigarettes rarely remains alight when discarded. 'Tailored' cigarettes, however, can remain alight for a considerable time and are the probable cause of many fires in the fifty years since they became fashionable and the moors became more accessible. (This is well recognized in Canadian National Forests. 'Tailored' cigarettes burn much longer when discarded than home-made ones or pipe ash, and are a much greater fire hazard.)

It is not certain that glass bottles or lightning have caused fires. Sparks from steam trains appear to be unimportant, but some deliberate arson on certain moors appears probable.

### Frequency of Fires before 1900

There have been many hundred fires in this area, but there are several reasons for believing that there were few major fires before 1900. Even to-day fires are poorly recorded, but there have been hundreds; for example, 700 fires were reported to Derbyshire Fire Brigade during September 1-11, 1959 (*S.T.*, September 12, 1959). In this article, a major fire is defined as one which burned for at least two days; it is thought that this is long enough for the fire to penetrate the peat and destroy the root zone; observation has shown that a fire can burn for more than a day and still be confined to the surface litter.

Prior to Parliamentary enclosure of the moors (1760-1855), the whole area was utilized by tenants of the adjacent farm-land. Sheep were 'staf-hearded' on 'sheep-walks' on the commons and wastes by flock-masters. The customary sheep-walks are noted in thirteenth century deeds for Midhope, Moscar, and elsewhere<sup>1</sup>; there is a map of Bleaklow and adjacent areas which shows the whole moor as a series of walks<sup>2</sup>. Cattle were stinted on customary beastgates, sometimes called 'summerings', and women milked cows and ewes on the moors<sup>3</sup>. Goats and horses were also kept<sup>4</sup>. Bracken, rushes, heather, second-growth timber, grass sods, bilberries, millstone, and other stone materials were carefully utilized. The whole was so carefully protected by intricate manorial rights and regulations that fires would be extremely rare. Small fires were specifically forbidden in some parishes to minimize the risk of uncontrolled fires which one might expect from time to time. One verdict of Sheffield Manorial Court, 4.10.1733, forbade the burning of bracken, which had several economic uses, such as bedding animals down. Elsewhere the firing of turf, sods, soil, and heather is specifically forbidden. Rights were known as Fernary, Furbary, etc.<sup>5</sup>.

Table 1. THE FREQUENCY OF FIRES

Date	Location	Source*	Remarks
1762	Broomhead Moors	Hunter (450)	Several thousand acres reduced
1826	Broomhead Moors	<i>S.I.</i> , 5.7.1826	—
1868	Hallam Moors Moscar Moors	Hunter (460) Hunter (460)	3,000 acres Burnt for more than two weeks
1887	Midhope Moors	Wood (109)	Burnt for several weeks, but could not have been extensive
1921	Big Moor Hallam Moors Houndkirk Moor	<i>S.C.R.</i> , 1922 (122) <i>S.C.R.</i> , 1922 (122) <i>S.C.R.</i> , 1922 (122)	Froggatt Edge Wyming Brook area —
1933	Leash Fen	<i>S.C.R.</i> , 1934 (96)	East of Gardoms Edge, 100 acres
1935	Baslow East Moor	<i>S.C.R.</i> , 1936 (147)	Gardoms Edge area, 300 acres. Three days burning
1938	Big Moor	<i>S.C.R.</i> , 1939 (171-3)	Nearly all the moor
	Hathersage Moor	<i>S.T.</i> , 9.5.38	"2,000 acres"
1939	Pike Lowe	Broomhead Keeper	Near the summit
1947	Broomhead Moor	Broomhead Keeper	Burned for 10 weeks
1948	Big Moor	<i>S.C.R.</i> , 1950 (181)	800 acres burnt below White Edge
	Hallam Moors	<i>S.C.R.</i> , 1949 (161)	Below Stanage Edge
	Hathersage Moor	<i>S.C.R.</i> , 1949 (161)	Near Carl Wark, 0.5 sq. mile
	Houndkirk Moor	<i>S.C.R.</i> , 1949 (161)	—
	Totley Moor	<i>S.C.R.</i> , 1949 (161)	Brown Edge, 300 acres
1949	Totley Moor	<i>S.C.R.</i> , 1950 (181)	800 acres burnt
1953	Leash Fen	<i>S.C.R.</i> , 1954 (110)	East of Gardoms Edge, 300 acres
1959	Baslow East Moor	Observation	Much of the moor
	Beeley Moor	Observation	Whole moor
	Brampton East Moor	Observation	A few acres
	Burbage Moor	Observation	Whole moor
	Hathersage Moor	Observation	Almost all the moor
	Moscar Moor	<i>S.T.</i> , 28.8.59	Upper Rivelin, south side
	Totley Moor	<i>S.T.</i> , 15.9.59	Almost all the moor

\* Full titles for books occur in the text. G. H. B. Ward's *Sheffield Clarion Ramblers Handbook* (*S.C.R.*) is the best single record and copies are kept in Sheffield City Library. Newspapers quoted are the *Sheffield Independent* (*S.I.*), *Sheffield Telegraph* (*S.T.*), and *The Star* (*S.S.*). Pages in parentheses.

Enclosure of the moors replaced this communal system with a different economy based on private grouse breeding. On such areas which are still private, being owned by water-boards or individuals, there are still no recorded fires; for example, on most of the Langsett, Hallam, and Derwent Moors, and the Chatsworth Estate.

The introduction of 'moor-management' by game-keepers led to the exclusion of both human and animal life from the moors in favour of game birds. 'Muirburn', introduced around 1800, is the seasonal burning of patches or strips of heather, but this burns only the stems and foliage, and not the root system or the peat. These fires no doubt eliminated some plants from the flora, but their most important effect has been to deposit ash on the upper layer of the peat.

The economic exploitation of the moors before 1800, and the privacy imposed up to and after 1900, thus kept the fires to a minimum. There are three known exceptions, which are listed in Table 1 and below.

The first discovered record is that of the 1762 devastation of Ewden and Broomhead Moors (*SK.* 2295, \*2395):

"1762 was the driest summer since 1723. Everything burnt up, and the moors being on fire from Ewden to this (Broomhead) common and consumed several hundred acres. Cowel was for the most part on fire and almost all the moors in England and Wales"<sup>6</sup>.

1826 was a very dry year, and fires were widespread. They included a 20-mile wide fire in Aberdeenshire, blazes on many of the moors of southern Scotland and the Pennines, all the way into Derbyshire. A "scorched and arid plain" was made of much of the Broomhead Moors, burning several thousand acres. This latter fire was attributed by some to a bilberry gatherer knocking out her pipe on the dry peat<sup>7</sup>. Of these fires a reporter wrote:

"The fires have not only spread over a wide extent of surface, but burnt to a great depth, consuming not only the moss, but the peat underneath. In some places, where they reach a soft

sub-stratum, they run to a great length under ground, and break out at the surface at other spots<sup>18</sup>.

Hunter believed the Broomhead fire to have been an extremely rare occurrence. In 1868 there was a large fire to the west of Sheffield. J. Wood says it was on Bradfield Moors<sup>9</sup>, but it is probable that the 3,000 burnt acres lay:

"... betwixt Moscar and Hollow Meadows, Redmires, and the Wyming Brook... The conflagration lasted about a fortnight, the smoke and flames being visible at a great distance; and the smell of the burnt peat extended much farther"<sup>10</sup>.

This fire was attributed by some to bilberry gatherers taking revenge for being ejected from their traditional picking grounds. In 1887 there were fires on Midhope and Strines Moors, but details are lacking<sup>11</sup>. These are the only fires for which evidence has been discovered in nineteenth-century documents, but it is probable that there were lesser ones.

### Fires in the Twentieth Century

From 1921, the number of recorded fires has steadily increased. In 1921, fires occurred around Wyming Brook, below Stanage Edge, on Froggatt Edge, and on Houndkirk Moor. On the latter moor, the fire is believed to have been started by "a spark from a steam-engine at 5.30 a.m."<sup>12</sup>. In May 1938, 1,700 acres of Big Moor and 500 acres of Hathersage Moor were burnt in what is probably the largest single fire known in the area. It consumed nearly all the peat on Big Moor, and the smoke blackened Buxton, 12 miles to the west<sup>13</sup>. In 1939, according to Mr. H. Hemsley (head gamekeeper, Broomhead Estates), a fierce fire burnt for several weeks on Pike Lowe, Yorkshire. Across the valley, parts of Broomhead Moors were burnt by a fire which raged and smouldered for more than ten weeks in 1947. (Began September 19, and was finally put out in the new year; information supplied by Mr. H. Hemsley.) In May 1948, 300 acres of Totley Moor were devastated<sup>14</sup>, and in the following year 800 acres below White Edge were reburnt<sup>15</sup>; perhaps Ramsley Moor was burnt at this time.

A careful examination of the ground shows that there have been serious fires on other moors for which there is no documentary evidence, but these areas are not extensive. Some of the Chatsworth Estate (on Brampton East Moor, and immediately east of Harland Edge) has no peat under the heather cover in locations where one might expect to find it. Partly-healed patches on Hingliff Hill, Langsett, and elsewhere, show that the foregoing record is not complete. However, the information on the effect of fires which can be collected for 1959 more than compensates for this.

### The Fires of 1959

Derbyshire was Britain's driest county in 1959, and, after six dry months, fires swept the moors in September. At Redmires Dam, May–September was the driest period since records began in 1842. Light anticyclonic winds gave Sheffield 78 per cent (23.96 in.) of its average precipitation, and only 10 per cent of its September average total. The mean maximum temperature exceeded 60° F in six consecutive months, during which time there was only 6.58 in. of rain. The area missed all the main thunderstorms affecting the rest of Britain (*Meteorological Office Monthly Reports*, 76–7; 1959–60). The variable winds complicated the fire-fighting, and in some cases it was noted that the fires advanced both with and against the prevailing wind. Totley Moor burned for 6 days; Barlow East Moor for more than 10 days; Beeley Moor more than 4 days; and Burbage–Hathersage Moors for at least 4 days<sup>16</sup>. People attracted by the novel sight of parched reservoirs along with other tourists probably dropped cigarette ends which were the cause of the fires. They destroyed more moorland and consumed more peat than in any preceding year.

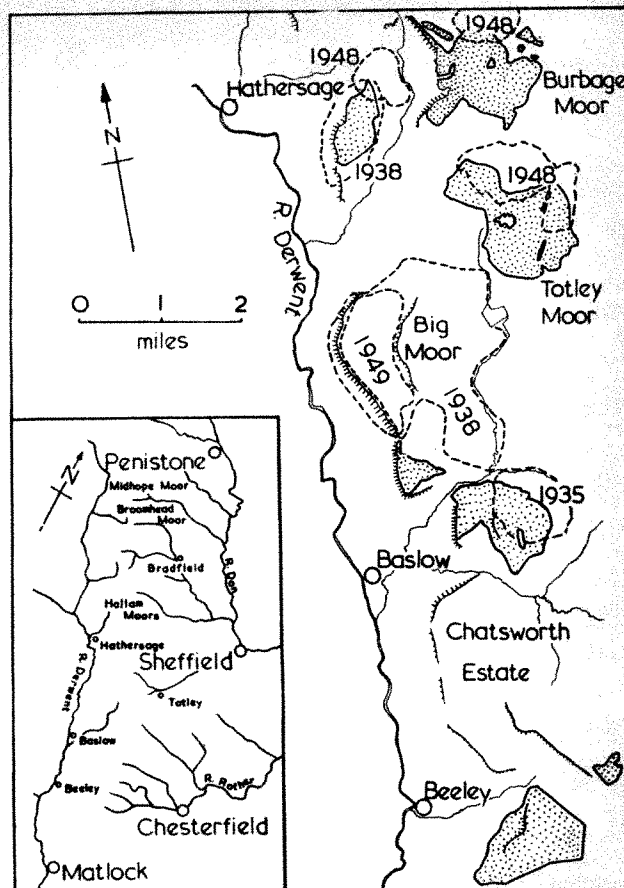

Fig. 1. Location map. The area of burning in 1959 is stippled

The burnt areas were mapped in 1961 at a scale of 2.5 in. : 1 mile. The information has been reduced and is shown in Fig. 1, which represents the approximate area devoid of blanket peat, where once there were considerable depths. It can be seen that these fires have an overall importance, and that they are relatively recent. The removal of the peat has had profound effects which can be observed at the present time on some of the moor burnt in 1959.

### Distribution of Intensity of Burning

Moss, Tansley and Pearsall directed attention to the botanical and geographical distinction between 'moor' on one hand, and 'moss' or 'bog', on the other<sup>17</sup>. In this article 'moorland' is used to denote a blanket bog which has lost its *Sphagnum* in favour of a heather or mixed vegetation; the peat is usually 3–5 ft. thick and is confined to slopes and ridges of the wet highlands of Britain. In contrast, a 'moss' is technically a true bog permanently waterlogged with acid peat often in excess of 20 ft. in thickness. In the investigation area, the toponymics 'moor' and 'moss' generally form a distinct demarcation of land above 1,000 ft. Fires normally occur on the moors and not on the mosses. There appears to have been a general upper limit to the burning of the order of 1,300–1,500 ft., which is perhaps a climatic limit. Most of the moors occupy ridges to the east and south of the main crest-line of Derwent Edge. The mosses have been fire-free because they occur in waterlogged swales which are either cut in shale, or choked with solifluction material which impedes the drainage and gives rise to bog conditions.

In the higher land at the latitude of Bradfield, there are mosses at 1,700 ft., and moors descending to 900 ft. below Broomhead Moors. At the latitude of Hathersage

the hills are lower, and White Path and Middle Mosses occur at 1,250–1,400 ft., while the burnt Burbage and Hathersage Moors are chiefly below 1,250 ft. At the altitude of Great Rowsley, there are no mosses and all the moors up to the 1,100 ft. summit are liable to be burnt. The mosses survive the burning, and are important in that they preserve some peat to regulate partially the run-off into adjacent reservoirs, and also preserve zones of peat in the lower areas which are otherwise denuded of peat.

The fires before 1920 were all north of Ringinglow, whereas the fires since 1920 have all been south of Ringinglow, which is probably a reflexion of the change in habits of Sheffield holiday-makers. Bradfield used to be a favourite 'resort' in the days of the wagonette; to-day the public moors around Hathersage are a greater attraction, with appropriately better public transport from Sheffield and cars using the A.623, A.624 and A.625. In both areas the fires are confined to the periphery of the peat.

The individual moors were burnt with varying degrees of thoroughness. Hathersage Moor was completely stripped; burning on Beeley Moor was patchy; and elsewhere holes and tunnels were burnt into otherwise untouched peat. The burning appears to have been limited only by the extent of the dry peat. Roads, natural rock outcrops, and even ploughed strips were not always effective limits to the burning.

#### Immediate Effect on the Flora

Even though special investigations are being made of the ecology of such burnt areas by botanists, it is necessary to note here the rapid rate of 'healing', which must be partially controlled by the completeness of the removal of the vegetation and peat. It is difficult to believe from the appearance of the vegetation cover that Big Moor was burnt in 1949, or that many parts of Pike Lowe's peat and vegetation cover were burnt in 1939.

There is a considerable range in the time taken for the moors to regain a reasonable cover. On Beeley Moor, *Eriophorum* spp. has spread over huge areas, to the general exclusion of other species. This rapid extension has been both by seeding and vegetative reproduction. Elsewhere, *Calluna vulgaris* is the main colonist using both methods of regeneration. On Birchen Edge there are several species involved in the production of an almost complete ground cover:

*Salix atrocinerea*  
*Betula pubescens*  
*Sorbus aucuparia*

*Calluna vulgaris*  
*Deschampsia flexuosa*  
*Agrostis tenuis*  
*Holcus mollis*

*Polytrichum commune*  
*Polytrichum piliferum*  
*Pohlia albicans*  
*Ceratodon purpureus*

*Chamenerion angustifolium*

The trees occur in areas not occupied by moss and grass, often adjacent to relict patches of woodland, while the mosses and grasses form large attractive splashes of varied greens across most of the dark, burnt moors.

Areas at a similar height on Hathersage Moor are still bare. On Big Moor, a close examination of the heather cover reveals that, after 15 years, the cover is fairly complete but still rather sparse in places. On Pike Lowe, considerable areas have been recolonized by heather and grasses, but the summit is still bare owing to its exposed nature. Similarly, near Broomhead Shooting Lodge, grass and heather, both sown and planted, and rows of straw-bales have been introduced to reduce the continuing erosion of the regolith, but to no avail. Apparently the rate of healing varies considerably from place to place, but it can be said that within 3–5 years most areas have a shrub or herbaceous cover.

When the colonizing is complete the rather monotonous sweep of each moor takes on a superficial appearance of uniformity, but firing creates one obvious but vital difference: beneath unburnt moors there is a peat layer,

while beneath burnt moors there is not. At the junction of these zones, the peat may remain in isolated mounds, revealing the depth of the former peat blanket. The past 50 years has seen a considerable retreat of the peat fringe in the areas which have been thoroughly burnt. (It seems probable that the peat fringe extended to lower altitudes prior to the advance of agriculture towards the moors, but much work remains to be done on this aspect.)

#### Changes on the Mineral Surface revealed by the 1959 Fires

The effects of fires prior to 1959 have escaped investigation, but the effects of the abnormally fierce and extensive 1959 fires can be taken as illustrative of the changes which can be made. The extensive desolate tracts are the most obvious short-term scenic change, and their barrenness has permitted several forms of erosion and deposition to develop.

Little load is removed by streams flowing from peat-covered hills, while burnt areas lose considerable detritus in the form of ash, peat and sand. Removal of the peat reduces the water-storage capacity of a moor, and an accurate record of the moorlands which have lost their peat would probably reveal catchment areas with changed run-off characteristics. (Similar findings were made by Conway, V. M., and Millar, A., "The Hydrology of Some Small Peat Covered Catchments in the Northern Pennines", *J. Inst. Water Eng.*, 14, No. 6; October 1960.)

There have been no landslides, mudflows, or any other large-scale surface movements in the survey area. Large, smooth slopes are grooved with hundreds of braided rills and gulleys. In three years, they have cut 12–15 in. on Burbage Moor, while after 15 years on Broomhead Moor, channels many hundred yards long have exceeded 3 ft. in depth. Rivulets have filled holes made by wallers and road-makers, choked hollow packhorse ways and boundary ditches. Culverts under roads, for example, at Hell Bank Top (SK. 287681), are repeatedly blocked. Sand has ponded behind walls, creating small deltas such as the one north-west of Owl Bar below Flask Edge (SK. 292784). It is not known whether this new stream-load has had any effect on the principal rivers.

More impressive is the effect of wind. The sand and ash on the exposed moors are being constantly removed by the prevailing west winds. Hard frosts heave and loosen the upper few centimetres of soil, and this is, in due course, blown away, scouring the surface and etching long parallel grooves. All the ash on exposed summits was removed within 2 years. On Burbage Moor, the wind has lowered the surface and created a shallow pebble 'pavement', resting on hard clay or sand. Localized sand-storms during very strong winds have blotted out visibility over extensive areas. Dust clouds, similar to the clouds of air-borne ash experienced during the fires, are carried beyond the moors into residential areas; in May and June 1960 reddish dust enveloped Sheffield for several days<sup>18</sup>, and as late as June 1962 considerable clouds of dust were being blown into Totley and Ashover. There is no evidence of wind abrasion on rocks.

There are impressive depositional effects. Large sand-drifts block Houndkirk Road (SK. 287827), and walls on Beeley, Burbage and Totley Moors are almost buried (Fig. 2). Surviving patches of cotton-grass act as sand traps, which often display such dune features as parallel ripples, horned spurs, and barchan-like crests.

The actual heat from the fires has baked some soils red and yellow and these are quite distinct from the effects of podsolization. Fine-grained sedimentary and crystalline pebbles were exploded. Blocks of gritstone, possibly weakened by weathering, have disintegrated since the fires. Extensive areas of partly burnt peat were hardened, or reduced to a coke-like ash. (This is best seen near the ventilation shaft, Totley Moor: SK. 276794.) In 1938, the fire caused several large rock-falls from Froggatt Edge<sup>18</sup>.

Fig. 2. Dune-like developments on Totley Moor

All these features are small in themselves but the total effect is considerable. It is also conceivable that they could affect future interpretations of the surface of the soil: the sand drifts look like some periglacial sand pockets; the pebble pavement and soil colour could be identified as products of pedogenic processes; the exploded pebbles could be due to frost action. Holes in the peat made by fire sometimes become pools, which could be attributed to normal bog development. Patchy burning, creating an uneven surface, could be related to tunnel collapse beneath the peat, and so on.

#### Exceptional Nature of the 1959 Fires

Previous fires removed peat and stimulated erosion but there has been nothing so impressive as the 1959 fires.

An examination of pack-horse roads on Derbyshire moors in 1956-57 showed that the many miles of roads, which had cut down through the peat, were usually overgrown and had suffered little erosion or infilling<sup>20</sup>. Since most of these packways have been abandoned for more than 150 years, their condition must be indicative of little erosion during that period (Fig. 3), even though they cross moors, such as Totley Moor, which have been severely burnt prior to 1959. Since 1959, extensive lengths of packway have been choked with wind- and water-borne sand and ash. Following the snows of the 1962-63 winter, when snow still occupied the hollows, it was observed on Totley Moor that ash and sand, to a depth of 4 in., were washed in a uniform cover over the snow in a matter of days.

Below Brown Edge on Totley Moor a wall follows the 1,100 ft. contour for more than half a mile. It is a natural trap for all erosion on the hill which rises 150 ft. above it. Fig. 4 shows the result of a section cut through deposits trapped by the wall (Fig. 5) (SK. 291,3710).

Fig. 3. Blown sand in a pack-horse road on Beeley Moor

The original soil is a hard, iron-enriched, yellow compact sand. Above this, there is a mixed sand and stone deposit, 6-7 in. thick, which is probably wind and water transported. The zone is dark and confined by the ancient humus layer and the humus layer which has developed on the deposit, but above this there is 20 in. of loose, stratified, black and grey, wind-borne sand which has been deposited on both sides of the wall since 1959. From 1809, when the wall was erected, to 1959 about 7,000 ft.<sup>3</sup> of detritus had been trapped against the upper side of the wall; since 1959 more than 25,000 ft.<sup>3</sup> has been trapped excluding the material below the wall, and there are many miles of wall smothered in sand elsewhere. The erosion since 1959 has been phenomenal and the total effect really exceptional.

Fig. 4. Section through deposits below Brown Edge, Totley Moor. Dotted deposit is the 1959 wind-blown sand; the hatched zone is pre-1959 deposit

#### Revealed Periglacial Features

The removal of the peat permits an examination of the regolith on which the Pennine peat blankets rest. The barren landscape which is exposed must look, in some ways, as it did prior to the return of the flora in post-glacial times. We know almost nothing of highland conditions during the final phases of the Wurm period or up to the earliest discovered pollens at the base of the peat which date from perhaps 5,000 B.C.—a gap of more than 10,000 years—during which there appears to have been only a little rounding of the angular blocks which make up the chaotic periglacial landscape.

The block fields are the characteristic periglacial feature. Large areas of angular, frost-riven boulders have been revealed. They are concentrated on the upper parts of dipslopes and below the 'edges' (Fig. 6). On Beeley Moor, Baslow East Moor, Hathersage Moor, and Totley Moor there are whole hillsides strewn with blocks. It is difficult to conceive how much more blockfield remains beneath the Pennine Peat.

Some surfaces are free from boulders. Here bedrock may be at the surface (for example, east of Mother Cap, Hathersage Moor; above Wildmoorstones Edge; above Gardom's Edge), or there may be a considerable depth of regolith if it is developed on flaggy or shaley bedrock. The upland swales may have even greater depths of solifluction. It is evident that the considerable erosion

Fig. 5. Sand trapped against the 1809 enclosure wall on Totley Moor

Fig. 6. Typical burnt moorland, still bare after 5 years

during the Pleistocene was later arrested and replaced by processes of accumulation when the peat began to form.

### Conclusions

In the area there have been almost 30 fires which could be called disastrous. They have occurred mainly since 1920, on the fringes of the peat blanket. It is not possible to determine in detail how many acres suffered from these fires, but it is certain that there has been nothing to equal the 1959 fires. The depths of peat on most moors is imperfectly known and so it is not possible to quote amounts which have been removed.

The peat in many parts of Britain is being severely eroded by subaerial forces<sup>21</sup>, but the firing provides a method of erosion not previously emphasized. It removes whole tracts of peat and plant cover in a matter of days and permits intensive erosion for several years. Eventually the area is 're-vegetated' and the area usually resumes its previous appearance. However, where run-off and present-day erosion rates are used to establish the age of valleys, as in the case of Young's study of the Strines area<sup>22</sup>, great care must be taken to ascertain whether the area has been burnt; if it has, the rate of erosion might have been far from constant.

The rate at which plant life recolonizes the burnt moors varies, but even on the 1959 burnt areas the scars of firing are quickly being concealed. The removal of the acid peat should help the proposed afforestation of Big Moor, and it seems possible that it will permit more trees to grow

on moors protected by water authorities from browsing animals and further fires; already there is a considerable growth of birch and willows on parts of Ramsley Moor which is now owned by Chesterfield Water Board.

While general texts<sup>23</sup> scarcely mention the effects of major fires on the moors, it seems probable that the vegetation of the southern Pennine moors and elsewhere is, in part, pyrogenic, and it is equally probable that the role of fire will increase in importance, now that more and more moors are being opened to the public and week-end car excursions to the moors continue to increase in popularity.

A knowledge of moorland fires such as those discussed here should be of interest to ecologists, hydrologists, and geographers, and it is to be hoped that comparative studies will be made elsewhere.

<sup>23</sup> See, for example, Pearsall, W. H., *Mountains and Moorlands* (1950); he notes the contribution of fires to changes in bog vegetation (155-6) but nothing more.

## HIGH-RESOLUTION OBSERVATIONS OF THE RADIO SOURCES IN CYGNUS AND CASSIOPEIA

By PROF. M. RYLE, F.R.S., B. ELSMORE and ANN C. NEVILLE

Mullard Radio Astronomy Observatory, Cavendish Laboratory,  
Cambridge

DURING the initial testing of the new Cambridge radio telescope<sup>1</sup> some observations have been made of the radio sources Cygnus A and Cassiopeia A at a wavelength of 21.3 cm. Though the observations of the former source do not add greatly to the information which has already been obtained<sup>2-4</sup>, by fitting simple models to the observed amplitude-spacing curves, the results for Cassiopeia A are of considerable interest because the complexity of this source cannot be established without the adoption of a full mapping procedure.

The instrument consists of one rail-mounted and two fixed 60-ft. paraboloids along an east-west axis; by

combining the signals from the movable aerial with those from each of the two fixed ones two interferometric systems are obtained simultaneously. If the observations made of the same region of sky over a 12-h period are combined, two rings of a large equivalent aerial can be synthesized<sup>1,5</sup>. By repeating the observations with different positions of the movable aerial, all the rings can be synthesized to build up an elliptical aperture approximately 1 mile in diameter.

When observations are made of a source which is small compared with the reception pattern of each individual aerial, it is unnecessary to use all the spacings and a

Fig. 1. *a*, Equivalent grating aerial; *b*, section across the centre of the corresponding reception pattern with an aperture grading which falls to 30 per cent for the outermost ring (spacing = 7,050  $\lambda$ )

Fig. 2. Contour map of Cygnus A. The contour interval is 26,000° K. The beam to half power is shown in the corner of the map. The limits of the optical source are shown by the dotted ellipses

circular grating aerial may be synthesized as in Fig. 1*a*.

The reception pattern of such an aerial has circular grating responses surrounding the main beam, but these introduce no difficulties provided that the angular radius of the first of these responses is appreciably greater than the angular extent of the source under investigation, and that other sources in the vicinity are considerably weaker.

In the observations recorded here the two sources are contained within regions having diameters of approximately 1.8 and 5.0 min of arc, respectively, and measurements using 8 and 16 different aerial separations are adequate; four 12-h runs for Cygnus A and eight 12-h runs for Cassiopeia A were therefore made. The dipoles were orientated with position angle = 0°. The observations for each source were combined in *Edsac II* in a manner analogous to that used in an earlier survey of an area around the North Pole<sup>5</sup>, and the output maps were drawn automatically on a curve plotter attached to the computer. The maps shown in Figs. 2, 4 and 5 were obtained using a grading function which fell to 30 per cent at the edge of the aperture; this grading gives a reception pattern the width of which to half intensity is 23 sec of arc in right ascension and 23 cosec 8 sec of arc in declination with a first sidelobe response of

Fig. 3. Section along the major axis of Cygnus A. The co-ordinates (1950-0) of the peaks of maximum brightness are indicated, together with the integrated flux density from the different components. The separation of the major peaks is  $108 \pm 5$  sec of arc

5 per cent. The observations were also combined with uniform grading in order to provide slightly greater resolution so that an investigation could be made of structure which was barely resolved.

*Cygnus A*. The contour map is shown in Fig. 2, which also indicates the position of the optical galaxy; the relative positions of optical and radio sources are believed to be accurate to within  $\pm 5$  sec of arc in each coordinate. The section along the major axis (position angle = 109°) of the map obtained with uniform grading is shown in Fig. 3.

An examination of the distribution perpendicular to the major axis shows that for both the main components the distribution can be fitted by a Gaussian source which falls to half intensity at a distance of  $7.5 \pm 2.5$  sec of arc either side of the centre. The gradient of the outer edge of each component also corresponds to a similar distribution. As can be seen from Fig. 3, the inner gradients are less steep, and the central intensity falls to less than 5 per cent of that at the peaks. There is, however, evidence for a third component at  $\alpha = 19h 57m 43s$  which contributes about 6 per cent of the total flux density.

Fig. 4. Profiles of Cassiopeia A as presented by the automatic curve-plotter

Fig. 5. Contour map of Cassiopeia A showing also the main optical filaments. The contour interval is 3,000° K. The positions of some of the brighter stars in the field are indicated by crosses

*Cassiopeia A*. The map derived for the source in Cassiopeia is presented as cuts across the two-dimensional contour map in Fig. 4, which shows that the main feature of the source is a remarkable ring of emission containing localized peaks of enhanced surface brightness.

The results are also shown as a contour map in Fig. 5. An interesting feature of the source is the gap in the ring diametrically opposite to the most intense peak. A comparison has been made between the structure which is revealed in the radio map and the optical filaments in the source. The area shows considerable and uneven obscuration, but a number of filaments are distinguishable; the positions of a number of these were measured from a print of Baade's original plate and were corrected for radial expansion. It can be seen from Fig. 5 that the intense peaks of the radio emission do not coincide with any optical feature; the most prominent optical filaments which are visible in the northern half of the source lie just within the ring of enhanced emission, although one falls in the gap in the ring.

Although it is evident that the source shows considerable non-uniformity, 90 per cent of the radio emission can be accounted for by a spherical shell of uniform and

isotropic emissivity, having a shell thickness  $\delta r$ , where  $\delta r/r = 0.25$ . This thickness is greater than that of the region containing the optical filaments<sup>4</sup>. Superimposed on any such simple model there must be local regions of greater volume emissivity to account for the large peaks in the observed distribution. It seems likely that the region of enhanced emission seen near the centre of the source ( $\alpha = 23^{\text{h}} 21^{\text{m}} 11^{\text{s}}$ ;  $\delta = 58^{\circ} 33'$ ) is similar to those seen in projection around the edge of the source. The volume emissivity within these localized regions must be considerably greater than the average emissivity of the shell; in the case of the most intense region ( $\alpha = 23^{\text{h}} 20^{\text{m}} 55^{\text{s}}$ ;  $\delta = 58^{\circ} 32'.6$ ) this enhancement is approximately 20.

Theories of the emission of radio waves from the shells of supernova remnants have been proposed by van der Laan<sup>7,8</sup>, based on the compression of the surrounding interstellar medium by the expanding material. The observation that Cassiopeia A is a shell source the outer limits of which are rather accurately circular supports van der Laan's model, but the large shell thickness implies that only a small compression of the original interstellar magnetic field has occurred. The very great emissivity of the shell (some  $10^8$  times that of the inter-

stellar medium) can then only be explained if most of the high-energy electrons responsible for the emission originate within the supernova, as proposed by van der Laan for the early stages of the expansion.

There appear to be a total of some 10–12 localized regions distributed around the shell which have an even greater volume emissivity; these sources, which have typical dimensions of 0.2–0.3 parsec, might be associated with regions of greater magnetic field strength.

We thank the Director of the University Mathematical Laboratory for the use of *Edsac II*.

## OBITUARIES

### Prof. J. M. F. Drummond

WITH the death of James Montagu Frank Drummond, emeritus professor of botany in the University of Manchester, at his home in Exmouth at the age of eighty-three, British botany has lost an unusually well informed academic and practical exponent. He was born in 1881, the second son of J. R. Drummond of the Indian Civil Service. He is survived by his second wife, *née* Dorothy Maria Farrant. His first wife, *née* Agnes Marguerite Ives, died in 1923.

Drummond was educated at King's College, London, and at Gonville and Caius, Cambridge, where he had the distinction of holding the Frank Smart research studentship during 1904–6. His first appointment as lecturer in botany at Armstrong College, Newcastle upon Tyne (1906), was followed, in 1909, by his joining the staff of Prof. F. O. Bower in the University of Glasgow as lecturer in plant physiology. There he remained until 1921, his teaching on various branches of botany being much appreciated by his students. It was during this period that he produced his masterly translation and up-to-date annotation of an eminent—and extensive—German text, Dr. G. Haberlandt's *Physiologische Pflanzenanatomie* (*Physiological Plant Anatomy*), 1914. His academic work was interrupted by the First World War when he saw active service with the Highland Light Infantry in France and the Palestine campaign.

When, in 1921, the Scottish Plant Breeding Station was established at Corstorphine, Midlothian, Drummond was invited to become its first director. His botanical interests, always broadly based and liberal, now turned in the direction of genetics, with special emphasis on the improvement of cultivated plants. Under his care the new Station was staffed and organized and was soon known for its varied and progressive activities. His work in this new field is recorded in the annual reports of the Station and in various public addresses. But still further opportunities were to come his way. In 1925, he was appointed Regius professor of botany in the University of Glasgow, and in 1930 he became George Harrison professor of botany in the University of Manchester, a post which he held until his retirement in 1946. During this period the trustees of the former Manchester Royal Botanical Society made a considerable bequest to the University to promote interest in horticulture in the region. On the funds thus made available, Prof. Drummond purchased and developed in Cheshire what are now the Jodrell Bank Botanical Experimental Grounds, and he also established a University lectureship in horticulture and a system of training for student gardeners. All this was very close to his heart: he was a true lover of plants and gardens and possessed an unrivalled knowledge of species, both native and exotic.

Much of the effect of Prof. Drummond's work lay, not so much in what he achieved under his own name, but rather in what he did for others and enabled them to achieve. For example, he greatly assisted Prof. Bower in re-editing, and in incorporating new material in, the third edition of *Botany of the Living Plant*. To all, but especially to his younger colleagues and students, he was unstinting of his help and encouragement of their work. His outlook,

thinking and writing were of unusual clarity and perspicacity. He held firmly to the view that a university was not simply a seat of learning but essentially a place both for study and character formation. This led him, among many other activities, to continue his interest in military training, and from 1932 until 1945 he was officer-in-command of the University Officers' (Senior) Training Corps. During the Second World War this greatly enlarged unit, which he organized and commanded with distinction, functioned as the 61st (Lancs.) Battalion of the Home Guard.

C. W. WARDLAW

### Mrs. Dorothea Waley Singer

MRS. DOROTHEA SINGER, the widow of Prof. Charles Singer, the historian of medicine and science, died on June 24, 1964. She was well known in many countries especially for her work on early manuscripts dealing with science and medicine, and for her activities on various international bodies.

Dorothea Waley Singer, the eldest daughter of Nathaniel L. Cohen, and of Julia M. Waley, was born in London on December 17, 1882. In early womanhood she spent some years at Queen's College, London, and in 1910 she married Charles Singer, who was then engaged mainly in clinical and pathological work. Soon afterwards they both became interested in the history of medicine and science and in 1913 they presented a joint communication on the history of the *contagium vivum* at the International Medical Congress held in London in that year. In following years they wrote several joint papers, dealing mainly with medieval medicine.

Meanwhile, Mrs. Singer had been very actively engaged on studying the surviving medieval manuscripts in the British Isles which dealt with different aspects of science and medicine. In 1916 she presented before the History Section of the Royal Society of Medicine a very careful and detailed study of more than a hundred plague tractates of the fourteenth and fifteenth centuries. She had for some years been trying to catalogue and codify the manuscripts in Britain which bore in any way on science and medicine, and by 1919 she knew of more than 30,000 many of which were, of course, direct copies or variants. The full fruition of these investigations began to be seen in 1924, when the Union Académique Internationale published the first volume of her monumental catalogue of alchemical manuscripts in the British Isles. The first volume is a small work because it deals only with the comparatively few Greek manuscripts in Britain. But the three succeeding volumes (1928–31) deal with the vast number of Latin and vernacular manuscripts, and they form a catalogue of great complexity and scholarship which will remain a standard work.

Mrs. Singer had continued to work on plague tractates and in 1950 she published a definitive catalogue of Latin and vernacular works on plague which dated from before the sixteenth century and were extant in Great Britain. Her cumulative catalogue, dealing with all scientific subjects, forms a very large collection of cards, and microfilms of it are deposited in some of the great libraries of the world.

Apart from this work on manuscripts Mrs. Singer wrote several books and many papers in learned journals. In 1924 she published a very useful study of Ambroise Paré, together with a generous selection from his writings. Her important long paper on Sir John Pringle and his times gives much information which is not readily available elsewhere. For nearly twenty years she was intermittently engaged on a detailed examination of the works of Giordano Bruno, and in 1950 her *Giordano Bruno, his Life and Thought* was published. It is a very scholarly and illuminating investigation of the work of that complex personality. Her last book to be published was a translation from the German of Prof. Klemm's *History of Technology* (1959).

Mrs. Singer was also well known for her activities in various societies, British and international, and for her great interest in social work. She performed an important service in the placing of girl refugees from Nazi Germany as student nurses in British hospitals, and for many years she did much to stimulate the improvement of hearing-aids for the deaf. Along with her husband she for many years provided generous hospitality to numerous foreign scientists and scholars visiting Britain.

E. ASHWORTH UNDERWOOD

### Dr. I. J. Kříženecký

DR. I. JAROSLAV KŘÍŽENECKÝ, director of the Gregor Mendel Museum in Brno, died on December 21, 1964, at the age of sixty-eight. He was born and educated in Prague. Between the two World Wars his researches into animal breeding took him to the United States and to England. In 1921 he moved to Brno, where he was professor of animal breeding and genetics in the College of Agriculture until 1949. In the 1950's he won the admiration and friendship of many biologists both in Czechoslovakia and in other countries for his resolute defence of Mendelian genetics. When plans for a Mendel Museum were made in 1962, Dr. Kříženecký was chosen to direct the work. It is largely due to his untiring efforts that a Department of Genetics has been founded in the Moravian Museum and a Memorial Hall is being prepared for the forthcoming Mendel symposium this summer. Dr. Kříženecký worked very hard despite great and protracted suffering to make this symposium a worthy tribute to Mendel. It is sad that he has not lived to complete his work. Czechoslovak scientists have lost a dedicated scientist who, like Mendel, was a humble man and a great teacher.

R. C. OLBY

## NEW FELLOWS OF THE ROYAL SOCIETY

AT a meeting of the Royal Society on March 18, the following were elected to fellowship of the Society:

DR. G. D. H. BELL, director, Plant Breeding Institute, Cambridge, distinguished for his application of genetical science to the advancement of plant breeding.

PROF. R. E. BELL, Rutherford professor and director of the Foster Radiation Laboratory in McGill University, Montreal, Canada, distinguished for his contributions to nuclear physics, especially for his measurements of very short life-times and of the binding energy of the deuteron.

DR. S. BRENNER, member of the Scientific Staff of the Medical Research Council Laboratory of Molecular Biology, University Postgraduate Medical School, Cambridge, distinguished for his contributions to molecular biology, especially in the study of the genetic material and its control of protein synthesis.

DR. G. S. BRINDLEY, lecturer in physiology at the Department of Physiology, in the University of Cambridge, distinguished as a physiologist, especially for his contributions to the study of human colour vision.

PROF. B. N. BROCKHOUSE, professor of physics in McMaster University, Hamilton, Canada, distinguished for his pioneering work on slow neutron spectroscopy, and for the applications of this technique to lattice dynamics and spin-waves.

PROF. A. R. COLLAR, Sir George White professor of aeronautical engineering in the University of Bristol, distinguished for his contributions to aero-elastic theory, the engineering application of matrices, aerodynamics, and for his work on aircraft flutter and stability.

SIR EDWARD COLLINGWOOD, mathematician, Alnwick, Northumberland, distinguished for his contributions to the theory of functions, and in particular for his work on cluster sets of arbitrary functions.

DR. R. R. A. COOMBS, assistant director at the Department of Pathology in the University of Cambridge, distinguished for his contributions to the immunological study of cell surfaces, of congenitins and immunoglobulins, and of allergic phenomena.

PROF. K. G. DENBIGH, Courtauld professor of chemical engineering and director of the Chemical Engineering Laboratories at the Imperial College of Science and Tech-

nology, in the University of London, distinguished for his application of chemical thermodynamics and kinetics to the optimization and improvement of chemical reaction processes.

PROF. G. E. FOGG, professor of botany at Westfield College, in the University of London, distinguished for his work on the metabolism of the algae and especially on nitrogen fixation in the blue-green algae.

DR. C. E. FORD, head of the Cytogenetics Section, Medical Research Council Radiobiological Research Unit, Harwell, distinguished for his contributions to the cytogenetics of mammals, and for his studies of chromosomal abnormalities in man.

PROF. R. A. GREGORY, George Holt professor of physiology in the University of Liverpool, distinguished for his work on the mechanism of gastro-intestinal movement and gastric secretion.

PROF. DOROTHY HILL, research professor of geology in the University of Queensland, Brisbane, Australia, distinguished for her researches on Palaeozoic fossil corals, their stratigraphical implications and the geological significance of their distribution on a world scale.

PROF. A. W. JOHNSON, Sir Jesse Boot professor of organic chemistry and head of the Department of Chemistry in the University of Nottingham, distinguished for his work on the organic chemistry of natural products, especially that of vitamin B<sub>12</sub>.

PROF. R. V. JONES, professor of natural philosophy in the University of Aberdeen, distinguished for fundamental physical measurements by novel instruments of exceptional precision; and for application of scientific methods to defence.

PROF. C. KEMBALL, professor of physical chemistry in Queen's University of Belfast, distinguished for his application of modern physico-chemical methods to the study of adsorption and catalysis at metal surfaces.

DR. J. S. KENNEDY, senior principal scientific officer, Agricultural Research Council Unit of Insect Physiology, Department of Zoology, Cambridge, distinguished for his contributions to the problem of insect migration and for his studies of the physiology and behaviour of locusts and greenfly.

PROF. T. KILBURN, professor of computer engineering in the University of Manchester, distinguished for his contributions to the development, design and engineering of electronic digital computers and high-speed computer components.

PROF. H. L. KORNBERG, professor of biochemistry in the University of Leicester, distinguished for his work on the elucidation of metabolic pathways in micro-organisms and of the control mechanisms governing them.

DR. H. KRONBERGER, scientist-in-chief, Reactor Group, United Kingdom Atomic Energy Authority, Risley, Warrington, Lancashire, distinguished for his applications of physical science to all aspects of the United Kingdom programme for the development of nuclear power.

PROF. C. P. LEBLOND, professor of anatomy in McGill University, Montreal, Canada, distinguished for his work on the physiology of the thyroid gland, cell population kinetics and on the cytology of protein synthesis.

PROF. P. MAHESHWARI, professor of botany and head of the Department of Botany in the University of Delhi, India, distinguished for his outstanding services to the advancement of science in India and for his sustained contributions to the embryology of seed plants.

PROF. B. J. MASON, professor of cloud physics at the Imperial College of Science and Technology, in the University of London, distinguished for his experimental and theoretical investigations into the physics of clouds and the electrification of thunderstorms.

PROF. W. V. MAYNEORD, professor of physics applied to medicine, at the Chester Beatty Research Institute, in the University of London, distinguished for his applications of physics to medicine, especially in the identification of chemical carcinogens, the rationalization of radiation dosimetry and the assessment of radiation hazards.

SIR GILBERT ROBERTS, partner, Freeman Fox and Partners, London, distinguished for his contributions to

civil engineering by advancing the design of structures, particularly long-span bridges.

PROF. S. K. RUNCORN, professor of physics and director of the Department of Physics in the University of Newcastle upon Tyne, distinguished for his experimental and theoretical researches on the Earth's magnetic field and for his studies of the palaeomagnetic properties of rocks.

PROF. P. M. SHEPPARD, professor of genetics in the University of Liverpool, distinguished for his contributions to ecological genetics and the study of natural selection in animal populations.

PROF. K. STEWARTSON, Goldsmid professor of mathematics and joint head of the Department of Mathematics at University College, in the University of London, distinguished for his contributions to our knowledge of boundary layer flow associated with the movement of bodies through compressible and incompressible fluids.

PROF. J. M. THODAY, Arthur Balfour professor of genetics in the University of Cambridge, distinguished for his research on the action of radiations on chromosomes and for his experimental studies of the genetical effects of selection.

PROF. J. C. WARD, professor of physics in the Johns Hopkins University, Baltimore, distinguished for his work in quantum field theory, particularly with reference to the renormalization of electric charge.

PROF. G. B. WHITHAM, professor and head of the Department of Applied Mathematics in the Graduate Aeronautical Laboratories, California Institute of Technology, Pasadena, distinguished for his development of new theoretical methods of calculating shock waves and other related hydrodynamical phenomena.

PROF. G. WILKINSON, professor of inorganic chemistry at the Imperial College of Science and Technology, in the University of London, distinguished for his contributions to nuclear and inorganic chemistry, particularly in relation to the structure of organo-metallic complexes.

## NEWS and VIEWS

Chief Veterinary Officer of the Ministry of Agriculture, Fisheries and Food : Sir John Ritchie, C.B.

ON April 2 Sir John Ritchie retires from the post of chief veterinary officer of the Ministry of Agriculture, Fisheries and Food. His period of thirteen years in this office has been exceeded by only one of the previous eight holders of the Government's major veterinary appointment. John Neish Ritchie was born at Turriff, Aberdeenshire, in 1904, and obtained his professional qualifications at the Royal (Dick) Veterinary College and the University of Edinburgh. He held appointments with the City of Edinburgh, the County of Midlothian, and then in 1935 with the Department of Agriculture for Scotland in charge of the Tuberculosis Attested Herds Scheme. In 1938 Ritchie became a superintending veterinary inspector of the newly formed Animal Health Division of the Ministry of Agriculture and Fisheries; he was promoted in 1945 to deputy chief veterinary officer and in 1952 to chief veterinary officer. His name will always be remembered for his work in the eradication of bovine tuberculosis; thirty years ago 40 per cent of dairy cattle were affected with this disease, which has now virtually been eliminated. In the international field he has played a major part in keeping foot-and-mouth disease away from Great Britain, where there has been no case of this disease since 1962. In 1955 the Royal College of Veterinary Surgeons elected him a Fellow in recognition of special eminence in veterinary science, and in 1959 he became its president. He

was awarded the C.B. in 1955 and was made Knight Bachelor in 1961, and in that year, 1962 and 1965 he received honorary doctorates from the Universities of Liverpool, Toronto and Edinburgh. Sir John Ritchie is, in October 1965, to become Principal and Dean of the Royal Veterinary College of the University of London.

J. Reid

MR. JOHN REID, who is to succeed Sir John Ritchie as chief veterinary officer of the Ministry of Agriculture, Fisheries and Food, brings a ripe experience to the post. He was born in Berwickshire in 1906 of farming stock and was brought up in Perthshire, where he was educated at the McLaren High School, Callander. Having developed a keen interest in livestock, he entered the Royal (Dick) Veterinary College at Edinburgh, where he qualified as a member of the Royal College of Veterinary Surgeons in 1929. He gained the Diploma in Veterinary State Medicine in 1931. He worked successively with two local authorities, Midlothian and Cumberland, gaining wide experience with bovine tuberculosis and other diseases of the dairy herd, and with meat inspection techniques. In 1938, when the Animal Health Division was set up, Reid was appointed a divisional veterinary officer and as such worked in Breconshire, at the Ministry's headquarters in London and once more in Cumberland, where he was closely associated with the campaign against sheep scab—a disease which was eradicated from Great Britain in 1952. In

1952, on promotion to superintending veterinary officer, Reid returned to London. In the past twelve years he has taken increasing responsibility in connexion with the control of animal diseases, particularly those of poultry. In 1963 he was appointed as the first director of veterinary field services, a post parallel to the directorship of the veterinary laboratories. Reid's career has progressed steadily to the post of chief veterinary officer in which he will be professional head of some 550 Civil Service veterinarians in the field, the Veterinary Laboratories and the Veterinary Investigation Service.

#### Biochemistry in King's College, London:

Prof. H. R. V. Arnstein

DR. H. R. V. ARNSTEIN, a member of the scientific staff of the Medical Research Council at the National Institute for Medical Research, has been appointed to the chair of biochemistry in King's College, London, in succession to Prof. H. Harris, who has been appointed Galton professor of human genetics at University College, London (see *Nature*, 187, 286 (1960); 198, 1148 (1963)). Dr. Arnstein, a graduate of the Imperial College of Science and Technology, London, was one of the original team working on the structure of penicillin under Sir Ian Heilbron and Dr. A. H. Cook. After spending a year as a Post-doctoral Fellow at the University of Rochester, New York, he joined the Biochemistry Division of the National Institute for Medical Research at Hampstead in 1948 and collaborated with Dr. A. Neuberger on glycine metabolism. In his work on penicillin biosynthesis, and more recently on protein synthesis, he has been one of the leaders in the application of radioactive isotopes to biochemical problems. Dr. Arnstein has also been an active officer of the Biochemical Society, having served both as meetings secretary and as committee secretary, as well as being for several years a member of the Editorial Board of the *Biochemical Journal*.

#### Applied Physical Sciences in the University of Reading:

Prof. P. D. Dunn

MR. P. D. DUNN, principal scientific officer in the Applied Physics Group of the Atomic Energy Research Establishment, Harwell, has been appointed to a professorship of applied physical sciences in the University of Reading. Mr. Dunn gained B.Sc. degrees at Nottingham (1950) and London (1951). In 1950 he joined the Linear Accelerator Group of the Atomic Energy Research Establishment at Malvern, where he was concerned with various problems of electron linear accelerators and a design study of a linear magnetron. The Group moved to Harwell in 1953 to build a proton linear accelerator, and his particular interest was in systems of coupled resonators for acceleration from about 150-MeV upwards. In 1957 he was much involved in the design studies leading to the choice of a constant gradient proton synchrotron (*Nimrod*) for the National Institute for Research in Nuclear Science, and he set up a group to design, construct and commission the radiofrequency accelerating system. Concurrently, he started an entirely separate programme of work on the investigation of thermoelectric, thermionic and magnetohydrodynamic methods of producing electricity directly from heat, and the consideration of feasibility in relation to reactors. In 1960 he was promoted to a Band post (senior principal scientific officer equivalent) as group leader of the two groups. In September 1963, after the successful commissioning of *Nimrod*, he again became a full-time member of Harwell staff and the direct conversion studies were somewhat broadened in the Applied Physics Group which he led. The factors which have contributed to the undoubted success of so many activities are originality, a sound knowledge of physics and engineering, and the ability to direct and inspire others. Besides having a general interest in further education Mr. Dunn has been greatly concerned with the training of engineers at Harwell. He has frequently

lectured on engineering and allied topics at training courses and has directed particular attention to the training and supervision of young engineers who have worked in his group on various problems of engineering physics. He is an associate member of both the Institution of Electrical Engineers and the Institution of Mechanical Engineers.

#### The Linnean Gold Medal and the H. H. Bloomer Award

DR. J. HUTCHINSON, lately keeper of museums of botany, Royal Botanic Gardens, Kew, and Dr. J. Ramsbottom, lately keeper of botany, British Museum (Natural History), has been nominated for the award of the Linnean Gold Medal for 1965. The Linnean Gold Medal, the Society's highest award, is awarded annually in recognition of the recipient's services to science. Mr. E. C. Wallace has been awarded the H. H. Bloomer Award. This Award is given to an amateur naturalist in recognition of important contributions to biological knowledge. The presentations will be made at the anniversary meeting of the Linnean Society on May 24.

#### Relationship of Pharmaceutical Industry and the National Health Service

IN the House of Commons on March 3, the Minister of Health, Mr. K. Robinson, announced that he had decided to set up a Committee of Enquiry to examine the relation of the pharmaceutical industry in Great Britain with the National Health Service, having regard to the structure of the industry, to the commercial policies of the firms comprising it, to pricing and sales promotion practices, to the effects of patents, and to the relevance and value of research. The Committee would draw up recommendations based on its findings. In reply to questions, Mr. Robinson added that he thought it would be impossible to examine British pharmaceutical companies which were subsidiaries of American companies without examining the relation between the two; the establishment of the Committee had been welcomed by the industry, with which there had been informal consultations.

#### The Science and Technology Bill

AT the report stage of the Science and Technology Bill in the House of Lords on March 9, the Parliamentary Secretary to the Ministry of Technology, Lord Snow, said that, to meet certain objections raised by Lord Bridges, the Government was making suitable administrative changes. The Science Research Council would have delegated authority to approve projects for grants up to £100,000 and also power to authorize the creation of new posts in its laboratories to a level equivalent to senior principal scientific officer in the Civil Service. As regards the National Institute for Research in Nuclear Science, the Science Research Council would replace the Atomic Energy Authority and approval of the Department and of the Treasury would only be required for items of expenditure exceeding £100,000. Lord Snow also met Lord Bridges's views by moving an amendment giving effect to the Government's decision to authorize the Science Research Council to recruit new staff to the Rutherford Laboratory of the Institute on terms enabling them to be members of the Atomic Energy Authority's pension scheme if they so chose. It was not intended to apply this provision to the Daresbury Laboratory, and it was not intended to make any difference in terms of employment for those recruited under the Atomic Energy Authority's scheme if they went to other employment under the Science Research Council. At the third reading on March 11, Lord Bridges questioned the wisdom of excluding the 100 members of staff at Daresbury from the Atomic Energy Authority's pension scheme if they wished to join. Lord Snow replied that this was an administrative decision. The Bill, as amended, passed its third reading, and was returned to the House of Commons, where the Lords amendments were agreed on March 15.

### Desalination Research

IN reply to a question in the House of Lords on March 11 regarding progress in the problem of desalting water, Lord Snow said that the Water Research Association had made good progress in studying the economic factors underlying the provision of sweet water, and a mission was to leave shortly for the United States for discussions with the Office of Saline Water. The Committee on Desalination Research had considered a research programme in conjunction with industry, and the Atomic Energy Authority had undertaken work on the use of nuclear energy for a desalination plant. The Committee and the Authority had watched closely work in the United States and elsewhere. British industry had already established, primarily for arid areas, a commercially proved method for converting sea-water into fresh in the multi-stage flash evaporator which was regarded as the most efficient in use to-day. Over the past 10 years British firms had supplied some 40 installations to various parts of the world, representing more than 70 per cent of the land-based plants in operation. The Government recognized the need to support research to maintain Britain's lead in a potentially growing export market, and the Minister of Technology hoped to make a statement fairly soon on plans for increasing the scale of effort on desalination research. Lord Snow said he was aware of the design studies at the Oakridge National Laboratory of the Atomic Energy Commission in Tennessee for a desalting plant with a capacity of 20 million gallons a day, with a possible increase of up to 50-100 million gallons a day. Co-operation was continuing in basic research, but Britain's effort would have to be increased if she were to maintain her present strong position.

### British Space Research

IN written answers in the House of Commons on March 5, the Secretary of State for Education and Science, Mr. A. Crosland, stated that the 3 scientists and 4 engineers in the Space Research Management Unit of his Department were the only ones engaged on space research and directly responsible to him. They would be transferred to the Science Research Council when that Council was formed. The Convention establishing the European Space Research Organization came into operation in March, 1964, and a financial protocol provided for a programme of space research (with sounding rockets and satellites) over the 8 years up to 1972. The programme for 1965 provided for launching 33 experiments in 14 payloads with sounding rockets. Contracts were being placed for 27 *Centaure* rockets from Sud Aviation de France and 20 *Skylark* rockets from the British Aircraft Corporation, and a contract for a satellite to investigate solar X-rays and cosmic radiation (to be launched in the spring of 1967) was being negotiated with Hawker-Siddeley Dynamics. Preliminary design studies had been completed for a polar ionospheric satellite to be launched towards the end of 1967 and tenders for its development invited. A large satellite of stellar astronomy experiments was scheduled for launching in 1968-69 and preliminary proposals for payloads were being considered. The Organization had established a space technology centre in the Netherlands and was establishing a space laboratory nearby. A data centre was being established in Germany and a launching range at Kiruna in Sweden. The Organization awarded fellowships to enable space scientists from member states to study in other member states or, under an agreement with the National Aeronautics and Space Administration, in the United States.

### Co-operation in Pharmacology between Milan and Buffalo

ARRANGEMENTS have been concluded for a close working relationship between the Institute of Pharmacology of the University of Milan (director, Prof. E. Trabucchi)

and the Department of Biochemical Pharmacology of the State University of New York at Buffalo (chairman, Prof. J. F. Danielli). The arrangements were evolved after a visit by Prof. R. Paoletti to Buffalo, and a visit by Dean D. H. Murray of the School of Pharmacy at Buffalo, together with Prof. Danielli, to Milan. Collaboration between the Institute and the Department will involve exchange of staff, of research students and of technicians, the sharing of certain equipment, and the organization of a joint symposium annually. In 1965 the first symposium, on "Cell Permeability and Transport Phenomena", will be organized from Milan (secretary, Dr. L. Bolis, Via Alamanni, 19, Milan, Italy). The 1966 symposium will be held at Buffalo on "Drugs Affecting the Immune Response", and the 1967 symposium will be held at Milan on "Peptides".

### New Museum and Art Gallery, Doncaster

H.R.H. PRINCESS MARGARET, COUNTESS OF SNOWDON, accompanied by the Earl of Snowdon, officially opened the new Museum and Art Gallery, Doncaster, on October 30, 1964. The new building cost just more than £291,000 and replaces the old museum and art gallery, now demolished, which was housed in an eighteenth-century building for 55 years. The new building consists of a main exhibition block on two floors, the ground floor being Museum and the first floor Art Gallery, with a part used temporarily for costume and uniforms. About half the Art Gallery is air conditioned. Attached to the main block is a separate wing containing the administrative offices, laboratories, store-rooms and workshops.

### Western Australian Museum, Perth

THE Western Australian Museum has received many objects from the wrecks of the Dutch East Indiamen of the seventeenth century, now lying on the sea-bed at no great distance from the shore. The Museum has been kept fully informed of this interesting work, but there is no existing legal provision which would enable the State to control the recovery of the material from these ships, which antedates Captain Cook by more than 100 years, and is thus of great interest in early Australian history. The objects already handed over to the State collection include an astrolabe, two apothecary's mortars, a protractor and a pair of navigator's dividers. The annual report of the Museum for 1963-64 includes a very useful list of type specimens in the zoological collections (Pp. 46. Perth: Western Australian Museum, 1964).

### The Museums Journal

THE *Museums Journal* for December 1964 (3, No. 3) includes an interesting and useful paper on typography in museums, and emphasizes the importance of the visual impact made by a wise selection of printed display matter. The prehistoric collections at the National Museum in Prague are described especially from the point of view of modern display. The remainder of the issue gives an account of the 1964 annual conference at Nottingham and includes a verbatim report of the presidential address by Dr. Dilwyn John. The *Journal* is produced in the attractive format which it has used during the past few years.

### Man

THE journal *Man* for November-December 1964 contains a number of important articles. On the social anthropological side there are papers on "Networks in Indian Social Structure", by Prof. M. N. Srinivas and André Bételle, and on "New Guinea Highland Models and Descent Theory", by Dr. R. F. Salisbury. Two accounts of iron smelting, one in north-east Nigeria and the other in Zambia not far from Livingstone, are also of special interest. In Nigeria the ore is magnetic iron ore, said by Przeworski not to be suitable for smelting, though David Livingstone described cases where it was

used as long ago as 1874. The magnetite is mixed with charcoal in a special furnace and duly fired. When trade started with western Europe the local smelting nearly ceased, but the imported steel was of such a poor quality that it has all started up again. The Zambia example from a site at Mr. Strydom's farm some 8 miles from Livingstone is not dissimilar. But no mention of the kind of iron ore used is given. Smelting has been observed (Burkitt, M. C., unpublished) at Serenje, also in Zambia, but a good way north of Livingstone. Here the ore was a carbonate and hence much more easily smelted. There is plenty of interesting material in this number of *Man*, but the attention of all anthropologists should be especially directed to the long and sympathetic obituary of the late Lord Raglan by Prof. C. Daryll Forde.

### Archaeological Excavations

A MEMORANDUM on the subject of safety precautions in archaeological excavations has been prepared by the Council of British Archaeology. It will act as an *aide-mémoire* to site directors and supervisors of archaeological excavations and also give valuable information to societies for whom they may be working. Copies (6d. plus postage) can be obtained from the Council of British Archaeology, 10 Bolton Gardens, London, S.W.5.

### The Acorn Lectures

VOLUME 2 of the Acorn Lectures, delivered at the A. D. Little Research Institute, Inveresk, contains abridged versions of four lectures, namely those of Dr. C. B. Amphlett on "Inorganic Ion Exchanges"; Dr. D. W. Pashley on "Electron Microscope Studies of Thin Films"; Prof. C. E. H. Bawn on "Stereoscopic Forces in Free Radical and Ionic Polymerization"; and of Prof. R. H. Thomson on "Black Pigments" (Pp. v+51. Inveresk: Arthur D. Little Research Institute, 1964). The lectures are not dated and the volume is edited by W. Banks.

### Metal-to-Metal Bonds

THE number of compounds in which metal-to-metal bonds have been shown to exist has greatly increased during the past few years. Such compounds may be divided into various classes, depending on the kind of interaction between the metal atoms which, for transition metals, may be direct or indirect, involving interaction via other atoms. Compounds of the first type show weak interaction or strong co-valent bonding, depending on the metal chosen, the oxidation state, and the attached ligands. Bonds between dissimilar transition metal atoms are less common than those between similar metal atoms, but this appears to be due to lack of purposeful effort to obtain such derivatives until recently. The extent to which co-valent, ionic, multi-centre, and indirect interaction occurs in these compounds has been discussed by Prof. J. Lewis of the University of Manchester and Prof. R. S. Nyholm of University College, London, in *Science Progress* (52, No. 208; 1964). The role of physical methods in assessing this is also reviewed.

### Soil Fertility and Elements of Rural Sociology in Africa South of the Sahara

IN its participation in the campaign against hunger, the Centre de Documentation Economique et Sociale Africaine has produced a bibliography entitled *Fertilité des Sols et Eléments de Sociologie Rurale en Afrique au Sud du Sahara*, by J. Lebrun and P. C. Lefevre (Pp. xvii+182. Bruxelles: Centre de Documentation Economique et Sociale Africaine, 1964. 500 francs). The object has been to collect as many as possible of the publications dealing with the soils and their fertility, especially as related to social problems, in order to assist in finding remedies for the problems concerning food production. There are 1,413 references to authors in alphabetical order, with the titles of their work, and a list of the periodicals

cited. These references have also been summarized by number under various heads such as agricultural development, soils, erosion, productivity, fertilizers and silviculture. There is a geographical index.

### Announcements

DR. W. C. ELMORE, chairman of the Department of Physics and professor of physics at Swarthmore College, Dr. F. Verbrugge, associate Dean of the Institute of Technology and professor of physics at the University of Minnesota, and Dr. L. R. Weber, department head and professor of physics at Colorado State University, have received distinguished service citations from the American Association of Physics Teachers, for their outstanding contributions to the teaching of physics in colleges and schools.

IN No. 789 in the Science Library Bibliographical Series some references to hovercraft from 1959 to 1964 are collected, both from books and periodicals, as well as reports and British patents specifications (Pp. 13. London: The Science Museum, 1964).

A SYMPOSIUM on "Pump Design, Testing and Operation" will be held at the National Engineering Laboratory during April 12-14. Further information can be obtained from the Organizing Secretary, Pump Symposium, National Engineering Laboratory, East Kilbride, Glasgow.

A GENERAL discussion of the Faraday Society on "The Kinetics of Proton Transfer Processes" will be held in the University of Newcastle upon Tyne during April 12-14. Further information can be obtained from the Assistant Secretary, the Faraday Society, 6 Gray's Inn Square, London, W.C.1.

THE first meeting of the Environmental Group will be held in the Imperial College of Science and Technology on April 9. Dr. Chrenko will address the meeting on the subject of "Freshness". Further information can be obtained from the Secretary, the Environmental Group, 16 Gloucester Place, London, W.1.

THE spring meeting of the British Society of Rheology on "The Flow of Powders and Granular Materials" will be held in Nottingham during April 7-8. Further information can be obtained from Mr. R. J. Cole, British Society of Rheology, Paint Research Station, Waldegrave Road, Teddington, Middlesex.

THE spring conference of the X-ray Analysis Group of the Institute of Physics and the Physical Society will be held in the University of Edinburgh during April 8-9. Further information can be obtained from the Administration Assistant, Institute of Physics and the Physical Society, 47 Belgrave Square, London, S.W.1.

A SYMPOSIUM on "Microbiological Deterioration in the Tropics", arranged by the Microbiology Group of the Society of Chemical Industry, will be held in London during April 8-9. Further information can be obtained from the Honorary Secretary, Society of Chemical Industry, 14 Belgrave Square, London, S.W.1.

A CONFERENCE on "Atomic Spectra and Radiation Processes", arranged by the Institute of Physics and the Physical Society, will be held in the Clarendon Laboratory, Oxford, during April 12-14. Further information can be obtained from the Administration Assistant, the Institute of Physics and the Physical Society, 47 Belgrave Square, London, S.W.1.

A RESIDENTIAL conference on "The Educational Requirements for the Professional Inspection and Quality Engineer", arranged by the Institution of Engineering Inspection, will be held at the Chelsea College of Science and Technology during April 11-14. Further information can be obtained from the Secretary, Institution of Engineering Inspection, 616 Grand Buildings, Trafalgar Square, London, W.C.2.

## OVERSEAS DEVELOPMENT AND SERVICE BILL

THE Overseas Development and Service Bill had an unopposed second reading in the House of Commons on February 24. The Minister of Overseas Development, Mrs. B. Castle, claimed that the Bill reflected the spirit of the discussions of the United Nations Conference on Trade and Development, and in moving its second reading explained that Clause 1 would assist good planning of colonial development and welfare by providing a year's overlap. Under this Clause, a further £50 million was provided for schemes financed by grants, and a further £20 million for loans, which with the outstanding amounts gave totals of £95 million for grants and £40 million for loans for the five years up to 1970, for a much smaller number of dependent territories than was covered by the £68.5 million and £32 million, respectively, provided for the three years 1963-66 under the 1963 Act. About thirty Governments still came within the scope of the Colonial Development and Welfare Acts, but Mrs. Castle thought it unlikely that actual expenditure would reach the ceiling of £25 million for grants for the first three years or £10 million for loans. The Bill also lowered the proportion of loans to grants and provided 70 per cent of this aid in grants, and she hoped to see the aid given in a form in which it could be speedily used for development.

Clause 2 of the Bill extended the provisions of the Overseas Service Act, 1961, which it replaced, under which 41 Governments and administrations had entered into agreements, and during the present year more than 11,000 officers were receiving benefits at a cost to the British Government of more than £16 million. During 1964, nearly 1,800 officers had been recruited by the Ministry and requests were still increasing. So far, the scheme had been limited to officers in the central public services of overseas Governments who were expatriate members of the Overseas Civil Service or expatriate contract officers appointed in the same way. Under this

Clause, the Minister was authorized, with the agreement of the Treasury, to extend the scheme to bodies and organizations overseas other than Governments who were employing expatriate officers, and to public or social services such as education or local government. Mrs. Castle said that while no general offer of help would be made, she would consider any requests which might be received on their merits. At the third Commonwealth Education Conference at Ottawa in August 1964, financial assistance had been offered towards the salaries of British teachers in overseas universities, and Mrs. Castle said she proposed to honour this undertaking through the extension of the aid scheme if the Bill were passed. She also emphasized that under the present scheme Britain had been at pains not to disturb the relation between overseas Governments and the expatriate officers they employed or to encourage any division of loyalty: she believed that this principle was right. Finally, she stressed the importance of enlarging and improving Britain's technical assistance.

The Bill was generally welcomed in a well-informed debate, and in winding up for the Government, the Parliamentary Secretary to the Ministry of Overseas Development, Mr. A. E. Oram, said that whereas under the 1963 Act £109 million was provided over three years for a population of 18.75 million, under the present Bill £135 million over five years was made available for 5.5 million. In a written answer on the same day, Mrs. Castle stated that bilateral economic aid to developing countries disbursed by the Government in 1963 amounted to £69.2 million in grants and £69.7 million in loans; for 1964 the corresponding figures were £81.9 million and £92.5 million. In addition, £13.3 million in 1963 and £13 million in 1964 were contributed in multilateral aid to international organizations and £5.7 million and £3.0 million, respectively, in multilateral aid in other ways. In 1963 private investment contributed about £65 million.

## PROBLEMS IN SETTING UP NEW UNIVERSITIES

A PAPER, *The Creation of New Universities\**, has been prepared by Dr. C. I. C. Bosanquet and Mr. A. S. Hall, based on a conference held at the University of Keele in July 1964. The conference was attended by representatives of all the existing new universities, and its purpose was to assess experience in planning, their physical layout and their academic strategies. Moreover, it was hoped that it would indicate the distinctive features of the British contribution to thought and design, and the common features of the technique used in establishing new universities and of the public pressures they illustrate. By and large, the authors conclude that disappointingly little use has been made of the opportunity for innovation. While the new universities are being created with remarkable speed and administrative skill, the range of subjects and types of teaching offered are unlikely to be altered significantly, but the kind of education hitherto confined to Oxford and Cambridge would be more widely distributed in the United Kingdom.

The sites so far chosen, with the exception of Warwick, lie on previously undeveloped land near the outskirts of towns of medium size, usually of historic interest, lacking major industry, but centres of local administration. The

older industrial areas, as a rule, have failed even to create a 'promotions committee'. The form of constitution evolved does not differ significantly from the constitution of twenty universities that have come into being in Britain since 1890. No daring experiments have as yet been tried—the main reason for this is regarded as being money: no university feels it can be independent of some kind of local support.

The four formal sessions of the conference covered the shaping of university development plans; curriculum and teaching; staff and student residential arrangements and social life; academic organization and university government.

While there was some sharp difference of opinion over internal organization, such as the extent to which it should centre on the college system or around schools of study, how far a university should impose its guardianship on its students, the degree of responsibility exercised by the University Grants Committee in regard to subjects of study and the relation of universities to Parliament, there were two main points of agreement. First, in development, strategy as well as tactics must be subject to continuous review, taking into account experience gained by the individual university, overall national needs, and the availability of reserves. Secondly, the greatest single difficulty has been inadequate reserves during the planning

\* *The Creation of New Universities*. (Based on a Conference at the University of Keele, July 14 to 18, 1964.) By C. I. C. Bosanquet and A. S. Hall. Pp. 14. (Keele: The University, 1964.)

period. The policy of the University Grants Committee to make no recurrent grants until a university receives its first students has postponed the appointment of key academic staff and necessitated the taking of decisions affecting the shape of a university for years to come, without the benefit of continuous academic advice. The very short period in advance for which capital grants have

been indicated has also delayed physical planning, and while it is essential that a new university should be assured of the sums of money that may be committed over each of the next five years, it would be still more helpful to indicate capital grants for ten years ahead. This financial assurance would also assist the start of the scholarly and scientific work of the university.

## REPRODUCTION OF THE AFRICAN ELEPHANT

CONTINUING his researches on the reproduction of the African elephant, Dr. J. S. Perry has examined eight foetal specimens collected during a two-year stay in Uganda\*. In one paper Prof. E. C. Amoroso and Dr. Perry have investigated the foetus *in utero* in a series ranging from the smallest, weighing only 2 g, to a near-term male of 120 kg. Adequate preservation in the field enabled the authors to describe not only the gross structure of the foetal membranes, but also the microscope anatomy of the placenta. The placenta of the elephant is zonary, but the allanto-chorionic villi are thinned or interrupted at intervals on the circumference of the chorionic sac. The large allantois is quadrilobular; its four sacs completely separate amnion and chorion, fusing with the former and meeting over the back of the foetus. A yolk sac was present in the youngest foetus of approximately two months gestation. The endodermal lining of the allantois bears a large number of mushroom-shaped "allantoic pustules" of unknown function.

The placenta is of the vaso-chorial type of Amoroso and Wislocki. The single-layered trophoblast is partly cellular and partly syncytial. Marginally maternal blood

exudes and is ingested by the cytotrophoblast. Centrally on the placental band active phagocytosis occurs. The elephant, hyrax and manatee "share a number of features in the arrangement of the foetal membranes and in the detailed structure of the placenta". Fourteen half-tone plates illustrate the work.

In the second paper, which is an extension of that published in 1953, Dr. Perry describes the reproductive organs of the female African elephant in foetal and young animals. The remarkable feature of the external genitalia is the similarity between male and female, in that the urogenital canal has been carried forward on the belly of the female to a point close behind the umbilicus, to a position similar to that of the male opening. The uterine horns undergo a ram's horn flexure, as in some ungulates, before uniting to form the body of the uterus, but the lumina remain separate for most of its length, and it is here that a one-sided conception occurs. The muscles of the external portion of the female genitalia are described. There are four plates of photographs of dissections and transverse sections of the reproductive tract, and seventeen text figures.

These papers give us for the first time a clear picture of the foetal membranes and placenta of the African elephant.

## CHEMISTRY AND PHYSIOLOGY OF 'DORMINS' IN SYCAMORE

### Identity of Sycamore 'Dormin' with Abscisin II

GROWTH-inhibitory compounds ('dormins') play a part in the regulation of bud-growth of some woody perennials<sup>1-6</sup>. In sycamore and in birch, a change from long-day to short-day conditions produces a marked increase in dormin concentration and the buds stop growing; dormin-containing extracts of leaves from birch plants grown under short-day conditions inhibit the growth and induce the formation of resting buds in actively growing birch seedlings maintained under long-day conditions. Owing to the considerable technical difficulties attending the determination of bud-inducing activity, concentration of dormin is usually estimated by inhibition of wheat coleoptile growth.

On the other hand, Addicott *et al.*<sup>6,7</sup> have isolated a plant hormone (abscisin II) from young cotton fruit by following its abscission-accelerating effect in cotton explants. Abscisin II was also found to inhibit oat coleoptile growth<sup>6,7</sup>. We have isolated the dormin from sycamore (*Acer pseudoplatanus*, L.) in crystalline form and have established its identity with abscisin II.

Chopped, dried sycamore leaves, collected in the autumn of 1963, were extracted at 4° with 4:1 (v/v) methanol:water. The methanol was removed under reduced pressure; the residual aqueous solution, decanted from the precipitated chlorophyll and acidified to pH 3.5, was extracted with ether. The dormin was extracted from the ethereal solution into aqueous sodium bicarbonate; continuous ether-extraction of the bicarbonate solution, adjusted to pH 8.0, removed most of the weakly

acidic inactive compounds; subsequent acidification to pH 3.5, ether-extraction, and evaporation of the ethereal solution yielded a rancid-smelling gum containing the dormin. This was dissolved in a slight excess of aqueous sodium hydroxide and treated with aqueous lead acetate which precipitated much inactive material, but left dormin in solution, from which it was extracted with ether after acidification. Further purification was by column chromatography (silicic acid, eluted with benzene-ether mixtures) followed by thin-layer chromatography ('Kiesel-gel-G'), developed with a propanol-butanol-ammonia-water (6:2:1:2 v/v) mixture. This gave a colourless partly crystalline gum, recrystallization of which from benzene yielded 260 µg of the dormin as minute platelets, m.p. ~ 160° (Kofler block), which sublimed at ~ 130° in a high vacuum. For abscisin II, Addicott *et al.*<sup>6,7</sup> give m.p. 160°–161°, subl. 120°.

Inhibitory activity was followed by germinating excised wheat embryos<sup>8</sup> for 48 h at 27° in the dark in 0.01 M sodium phosphate buffer (pH 7.4) containing the test material at five or more geometric dilutions. Probit percentage reductions in coleoptile length were plotted against log<sub>10</sub> concentration to give a straight line. The concentration reducing length by 50 per cent was used to compare the activities of the test material. We have detected only one compound showing high growth-inhibitory activity in sycamore leaves.

The molecular weight of the dormin, determined by mass-spectrometry, was 264, identical with that reported<sup>6,7</sup> for abscisin II. The infra-red spectrum (potassium

chloride pressed disk) was identical with the published spectrum<sup>6,7</sup> of abscisin II, except for the intensity of the peak at 1,155  $\text{cm}^{-1}$  (sycamore dormin, *vv*; abscisin, *m*); in the 2,000–1,500  $\text{cm}^{-1}$  region the dormin had  $\nu_{\text{max}}$  1,670 (*vs*, shoulder), 1,650 (*vs*) 1,630 (*s*, shoulder), 1,600 (*s*, sharp). In the ultra-violet, the dormin absorbed at 260 and 245 (shoulder)  $\text{m}\mu$  in neutral or acidified ethanol, and at 244  $\text{m}\mu$  (with a 20 per cent increase in the extinction coefficient) in ethanol made alkaline with sodium hydroxide. The sensitivity of the spectrum to pH, and a low end-absorption ( $\epsilon_{200} : \epsilon_{260} \approx 0.5$ ), are characteristic of the purified dormin. We were unable to measure the extinction coefficient, which was of the order  $\epsilon_{200} = 15,000$ . For abscisin II, Addicott *et al.*<sup>6,7</sup> report  $\lambda_{\text{max}}$  (methanol) 252  $\text{m}\mu$  ( $\epsilon$  25,200), which agrees with the  $\lambda_{\text{max}}$  of sycamore dormin in weakly alkaline ethanolic solution. Sodium borohydride in aqueous-ethanolic solution reduced the dormin slowly to a compound with  $\lambda_{\text{max}}$  268  $\text{m}\mu$  in acid solution and 252  $\text{m}\mu$  in alkaline solution. It has already been shown<sup>9</sup> that the biological activity of crude dormin extracts is slowly destroyed by treatment with sodium borohydride.

The dormin appears to be a carboxylic acid having in addition a hydroxyl and an unsaturated ketone function. Its methyl ester, prepared by treatment with ethereal diazomethane for 3 min at 0°, showed  $\nu_{\text{max}}$  3,245 (*s*), 1,710 (*vs*), 1,655 (*vs*), 1,630 (*m-s*, shoulder), 1,600 (*s*, sharp), 1,232 (*vs*), 1,157 (*vs*)  $\text{cm}^{-1}$ ; and  $\lambda_{\text{max}}$  (ethanol) 264 and 238 (shoulder)  $\text{m}\mu$ , unaffected by addition of acid or alkali.

From a comparison of the properties of the dormin and abscisin II, particularly the molecular weights, infra-red spectra and melting-points, we conclude that the two compounds are identical.

It has been pointed out by Osborne<sup>10</sup> that abscission is an unspecific phenomenon which can be induced by auxins, kinins and gibberellins. Growth inhibition is also rather unspecific. Both abscisin II<sup>6,7</sup> and sycamore dormin<sup>2,9</sup> have been shown to inhibit coleoptile extension, and the dormin has proved to have abscission activity<sup>11</sup>. The role of this type of hormone in the plant has still to be defined, but the presence of high levels<sup>9</sup> in leaves of sycamore during early September when resting buds have been formed, but long before the leaves fall, suggests that the term dormin may give a better description of function.

We thank Dr. A. Wardrop of the Forest Products Laboratory, Melbourne, and Dr. J. R. Price of C.S.I.R.O. Chemical Research Laboratories, Melbourne, for arranging a collection of leaves in Australia. We also thank Mr. S. French for help with the extractions.

## Action of the Sycamore 'Dormin' as a Gibberellin Antagonist

THE hypothesis that endogenous growth inhibitors may regulate dormancy was first put forward by Hemberg<sup>1</sup>, and recently additional evidence has been brought forward in support of the view that bud dormancy in sycamore (*Acer pseudoplatanus*) and birch (*Betula pubescens*) is regulated by endogenous inhibitors<sup>2,3</sup>. This evidence may be summarized as follows: (1) A consideration of the photoperiodic phenomena in seedlings of woody plants suggests that when the leaves are maintained under short-day conditions they exert an inhibitory effect on the shoot-apex<sup>4</sup>. (2) Investigations on the levels of the growth-inhibiting substances in seedlings of woody plants under different photoperiodic conditions have shown that greater amounts are present in the leaves and apical buds of sycamore and other species under short days than with long days<sup>3,5</sup>. (3) When inhibitor extracted from the leaves of birch is applied to seedlings of this species growing under long-day conditions, extension growth ceases and apparently normal resting-buds are formed<sup>3</sup>; similar results have recently been obtained with seedlings of sycamore and blackcurrant. Thus, the evidence that endogenous inhibitors may function as dormancy regulators is gradually accumulating, and hence they have been referred to as 'dormins'. The sycamore inhibitor preparations used in our tests do not appear to contain more than one inhibitory substance of high activity<sup>2</sup>.

The question arises as to the mode of action of dormins in the plant. Studies with partially purified preparations of the inhibitor from sycamore suggest that it does not interact competitively with indolyl-3-acetic acid (IAA) in the coleoptile test<sup>3</sup>, and this conclusion is consistent with the observation that application of IAA does not overcome the dormancy of buds. On the other hand, several pieces of evidence suggest that the inhibitor may be antagonizing the action of endogenous gibberellins in the plant. Thus, it is well known that gibberellic acid (GA) will overcome the dormancy of buds induced by short days in several woody species, including sycamore, birch and blackcurrant. Moreover, birch seedlings which have been induced to form resting buds by externally applied inhibitor will resume growth if GA is then applied, or if the GA is supplied simultaneously with the inhibitor the seedlings will continue in active growth<sup>3</sup>, so that the effect of the inhibitor is nullified. Experiments of this type do not easily lend themselves to precise quantitative treatment, however, and consequently a series of other tests has been carried out with the sycamore inhibitor, in an attempt to determine the nature of its interaction with GA; for example, whether it is: (1) acting competitively with gibberellins; (2) inhibiting gibberellin synthesis; (3) acting in some other way. A series of tests has been carried out with the *Avena* coleoptile and mesocotyl tests, using inhibitor extracted from sycamore leaves and partially purified by paper chromatography in isopropanol-ammonia water and butanol-ammonia-water by the method described previously. This method separates the inhibitor from phenolic material. Although some workers have reported a response of coleoptile sections to gibberellic acid, the response is usually slight or absent. However, if coleoptile sections are supplied with an optimal level of IAA (1.0 mg/l.), together with various concentrations of inhibitor, then the growth is markedly reduced by the inhibitor, but it can be restored to about the level of the IAA controls by simultaneously supplying GA (Fig. 1). Thus, although the coleoptiles do not respond to GA in the absence of inhibitor, in the presence of the latter they become GA-requiring. The shape of the curves suggests a rather specific interaction between the inhibitor and GA in this test.

Seedlings of dwarf mutants of maize and dwarf varieties of pea are frequently used for assay of gibberellin activity.

Fig. 1. Interaction between sycamore inhibitor and gibberellic acid in *Avena* coleoptile section test. All sections received indolyl-3-acetic acid at 1.0 p.p.m. The relative concentrations of the inhibitor are given

It was found that the inhibitor showed little activity when applied to dwarf mutants ( $d_1$ ,  $d_2$ ,  $d_3$  and  $d_5$ ) of maize, using the leaf section test, whether the inhibitor was applied alone or in conjunction with GA (except in the case of  $d_3$  mutants, where there was some inhibition of GA-stimulated growth). On the other hand, the inhibitor markedly reduced the growth of sections of tall (non-dwarf) maize, and this inhibition was almost completely overcome by GA (Fig. 2). By contrast, the sycamore inhibitor did not reduce the normal growth of dwarf ('Meteor') or tall ('Alderman') peas, but it markedly reduced GA-induced growth of both types of pea seedlings. The results of these tests are difficult to interpret, but in both species it would seem significant that the inhibitor is only active in reducing GA-induced growth.

In the foregoing tests, the sycamore inhibitor appeared to be interacting with GA in cell extension, and the following evidence suggests that it is also active in inhibiting cell division. Thus, liquid shake cultures of sycamore cambial tissue supplied by Dr. D. H. Northcote were established, using a modified Heller salt medium with added vitamins (but no coconut milk). When sycamore inhibitor was added to the culture medium cell division

Fig. 2. Interaction between sycamore inhibitor and gibberellic acid in test with leaf sections of a tall variety of maize, using the method of Frankland and Wareing (ref. 13)

was completely inhibited, and it was impossible to overcome this effect by supplying GA, although GA alone stimulates cell division in liquid cultures of this tissue<sup>6</sup>. Addition of IAA or kinetin to the culture solution reduced the effect of the inhibitor, but the form of the response curves suggested a non-competitive interaction.

Although the results with the *Avena* coleoptile test suggested a direct competitive interaction between the sycamore inhibitor and GA, other evidence suggests that possibly the inhibitor may affect hormone biosynthesis. Thus, it has been observed by ourselves for seedlings of sycamore and other species that there is a reciprocal variation in the levels of growth-promoters (both auxins and gibberellins) and of inhibitors under different day-length conditions, there being high levels of promoters and low levels of inhibitors under long days and vice versa under short days<sup>7</sup>. Libbert<sup>8</sup> and Dorffling<sup>9</sup> have suggested that the 'β-inhibitor' found in many plant tissues regulates auxin biosynthesis. Direct evidence in support of this hypothesis has been obtained by ourselves with birch seedlings, by applying inhibitor from leaves of this species, either in lanolin or in solution, to the leaves of the seedlings, when it was found that the levels of auxins and gibberellins both in the leaves and in the shoot apical region were markedly reduced. On the other hand, addition of the sycamore inhibitor to cultures of the fungus *Gibberella fujikuroi* did not appreciably reduce the yields of GA by the fungus.

It is known that gibberellic acid will stimulate the synthesis of α-amylase by isolated barley endosperms<sup>10</sup>, and interaction between the sycamore inhibitor and gibberellic acid has been studied using this test. The technique used was that of Nicholls and Paley<sup>11</sup>, in which sections of barley endosperm were placed in tubes containing a range of GA and inhibitor concentrations in various combinations. After incubation for 30 h at 25° C the sugar released into the solution was determined by modification of the Somogyi method, using a colorimeter. It was found that the sycamore inhibitor suppressed the production of reducing sugars when used in combination with low concentrations of GA, but this inhibition was partly overcome at higher concentrations of GA (Fig. 3). Hemberg<sup>12</sup> has reported that the 'β-inhibitor' from potato inhibits the activity of α-amylase, but tests with sycamore inhibitor gave negative results with preparations of α-amylase. Thus, the sycamore inhibitor appears to inhibit the synthesis of α-amylase, but not the action of the enzyme itself.

It is clear that considerable further work will be needed to elucidate the nature of the interaction between gibberellin and sycamore inhibitor, but the observation that GA appears to counteract the effect of the inhibitor and vice versa, in several different tests, strongly suggests that the inhibitor may function as a gibberellin antagonist *in vivo*.

Fig. 3. Interaction between sycamore inhibitor and gibberellic acid in synthesis of α-amylase by barley endosperm. The concentration of reducing sugar produced is a measure of the amount of α-amylase formed

We thank Dr. I. D. J. Phillips for several helpful suggestions in the preparation of this article.

## SYNCHRONOUS CULTURE OF STRAIN-L MOUSE CELLS

By DR. R. SINCLAIR and DR. D. H. L. BISHOP

Chemical Biology Unit, Zoology Department, University of Edinburgh

**M**ETHODS for the preparation of synchronously dividing mammalian cells already include the use of temperature shock<sup>1</sup>, the mechanical or enzymatic dislodgement of cells in mitosis<sup>2</sup>, and the blockage of protein or DNA synthesis by antimetabolites or excess of thymidine<sup>3</sup>. A method recently developed by Mitchison and Vincent<sup>4</sup> for making synchronous cultures of yeast and bacteria by sedimentation may also be adapted to the mammalian cell system and overcomes the problem of providing sufficient material for the biochemical investigation of the events of the cell cycle, and the problem of avoiding the chemical derangement of cell metabolism. The method is simple and consists of centrifuging logarithmically growing cells through a sucrose gradient, then reculturing the small cell fraction. We present an analysis of the application of this method to strain-L mouse cells growing in suspension in a chemically defined medium.

The medium was a modified form of the Waymouth MB 752/1 formula<sup>5</sup>, substituting the amino-acid mixture (Medium C) devised by Mohberg and Johnson<sup>6</sup>. Strain L cells grow continuously in suspension in this medium with a maximum mean doubling time of 36 h (ref. 7). A culture of high viability to begin the experiment was obtained by taking suspension-grown cells through one generation in monolayer roller culture, removing dead cells by a complete medium change, then resuspending by treatment with trypsin, in partially used medium<sup>8</sup>. Addition of fresh medium was made at a dilution ratio of 0.4 day<sup>-1</sup> to maintain exponential growth.

Cells ( $2 \times 10^6$ ) from this culture were collected by centrifugation (100g for 10 min) at room temperature, resuspended in 1-ml. medium and layered on the surface of 14 ml. of a 5–15 per cent linear sucrose gradient in a heavy-walled test-tube. The gradient was prepared aseptically with a gradient machine using 5 per cent (w/v) sucrose in 0.07 M sodium chloride and 0.01 M phosphate buffer, and 15 per cent (w/v) sucrose in 0.01 M phosphate buffer. The choice of the gradient around the isotonic concentration of about 10 per cent sucrose was dictated by the osmolarity which these cells can tolerate<sup>9</sup>. In order to minimize the formation of streamers, the 1-ml. layer of cells was carefully stirred into the upper part of the gradient to occupy twice its original depth and immediately centrifuged at 80g for 6 min.

After centrifugation it was observed that a proportion of the cells had formed a pellet at the bottom of the tube, but the remainder were distributed in a broad band occupying two-thirds of the gradient. A syringe fitted with a long needle was lowered mechanically into the suspension to remove the upper 1-ml. fraction of this band. These cells, equal to 4 per cent of the initial number, were washed once with used medium and resuspended in a mixture of 18 ml. of used medium, 2 ml. of fresh medium

and 1 drop of crystalline trypsin solution (50 µg/ml.) in a 50 ml. round-bottom flask under an atmosphere of 5 per cent carbon dioxide in air. A control preparation of cells was made by gently mixing all the cells remaining in the gradient, and washing and resuspending a small portion in the same way. Samples of both cell populations were retained for sizing by photography. The cultures were stirred magnetically at 200 r.p.m. at 37°, and were afterwards sampled and fed every 4 h by removing 1 ml. of the cell suspension and replacing it with 1 ml. of fresh medium. The atmosphere was flushed with 5 per cent carbon dioxide in air at each sampling, and 1 drop of crystalline trypsin solution was added every 24 h. The sample was counted, fixed in 4 per cent (v/v) formaldehyde in 0.9 per cent sodium chloride, and stained by the Feulgen method to measure the mitotic index.

A comparison of the diameters of selected cells and the control group is shown in Fig. 1. It is clear that the majority of the cells selected for synchronous growth were in the lower range of cell diameters. The mean diameters were 14.1 µ and 15.4 µ, respectively, and these differ significantly at less than the 0.1 per cent level. Fig. 2 illustrates the calculated number of cells present in each culture obtained by counting at least 1,000 cells per sample in a haemocytometer and correcting the actual concentration for the semi-continuous sampling schedule which was maintained. The cell concentration was well below the steady-state concentration which would be expected for this dilution ratio and, in any event, steady-state conditions would not have been achieved during the

Fig. 1. Frequency histogram of cell diameters. Logarithmically growing cells ( $2 \times 10^6$ ) were centrifuged at 80g for 6 min on a 5–15 per cent sucrose gradient. One ml. was removed from the top of the resulting cell band, added to 8 ml. of used medium and the cells recovered by centrifugation at 100g for 10 min. A sample was photographed and the cell diameters of 200 cells determined (continuous line). A control from the remainder of the cells on the gradient was similarly treated (broken line). Cell diameters are expressed as a percentage of the total

Fig. 2. Cell numbers and mitotic indices of synchronous and control cell cultures. Cells ( $8 \times 10^6$ ) separated on a sucrose gradient and freed from sucrose (Fig. 1) were suspended in 18 ml. used medium, 2 ml. fresh medium, 1 drop of trypsin solution (50  $\mu$ g/ml.) and gassed with 5 per cent carbon dioxide in air. Samples (1 ml.) were removed periodically, counted ( $\nabla$ , synchronous culture;  $\blacktriangledown$ , control culture) and fixed in 4 per cent formaldehyde for determination of the mitotic index by the Feulgen method ( $\circ$ , synchronous culture;  $\bullet$ , control culture). After sampling, 1 ml. fresh medium was added and each culture was regassed. The total cell number has been calculated by correcting the measured number of cells by the dilution factor.

period of the experiment<sup>7</sup>. The small loss of cells over the first 16 h in the synchronous culture probably represents dead cells which sedimented with the small cell fraction rather than cells damaged by the manipulations, since the control did not undergo a similar loss. Each

plateau on the synchronous curve represents the doubling of about 80 per cent of the cells present. The progressive loss of steepness in consecutive steps illustrates the expected decay in synchrony with time.

In estimating the mitotic index, late prophase, metaphase, and anaphase were scored for at least 2,000 cells per sample, and the results are shown in the lower curves in Fig. 2. After an initial delay in mitosis, the control index remained constant during the experiment, while the index in the test culture passed through a series of peaks corresponding to the steps in the cell count. Since the cultures were growing at the same overall rate, the total number of mitosis in each should be the same. This was not observed, because samples were removed every 4 h and mitosis of these cells probably occupies less than 2 h. An analysis of the degree of synchrony at each step (by Engelberg's method<sup>10</sup>) will be presented elsewhere.

While this method is not better than the best published methods of establishing synchrony in mammalian cells, its value lies in its simplicity, in providing at least two well-defined synchronous steps, and in the ease with which it can be scaled up to furnish sufficient material for biochemical analysis.

We thank Prof. J. M. Mitchison for facilities and advice, and the Nuffield Foundation for financial support.

## A NEW HAEMOGLOBIN, D IBADAN ( $\beta$ -87 THREONINE $\rightarrow$ LYSINE), PRODUCING NO SICKLE-CELL HAEMOGLOBIN D DISEASE WITH HAEMOGLOBIN S

By DR. E. J. WATSON-WILLIAMS\*

Subdepartment of Haematology, University College Hospital, Ibadan, Nigeria

AND

D. BEALE, D. IRVINE and DR. H. LEHMANN

Medical Research Council Abnormal Haemoglobin Research Unit, University Department of Biochemistry, Cambridge

AT University College, Ibadan, Nigeria, all blood donors are screened for abnormal haemoglobins to ensure that no blood from patients with haemoglobinopathies is transfused. The haemoglobin of a 25-year-old member of the Yoruba tribe showed on paper electrophoresis at alkaline pH a single band which was indistinguishable from that of Hb S (Fig. 1). He was working as a carpenter and there was nothing to suggest sickle-cell anaemia in his previous history or in his present state. On examination there was no palpable spleen, the haemoglobin-level was 14.8 g/100 ml. blood, and the percentage of reticulocytes was <1. The red cells sickled on incubation with 2 per cent  $\text{Na}_2\text{S}_2\text{O}_8$ , but the morphology was normal and no sickled cells were seen in the stained smear of peripheral blood. The findings were those usually met with in sickle-cell trait, the heterozygous state for the genes controlling Hbs A and S respectively. No Hb A was found, and the non-sickling haemoglobin if present had to have a closely similar or identical electrophoretic

mobility to Hb S. Of the family, one sister and the mother could be examined. The sister had the sickle-cell trait (A+S), while the findings in the mother were identical with those of her son. Her red cells sickled, and although on electrophoresis of the haemoglobin only a single band in the Hb S position was found, there was no evidence of anaemia or disease. The propositus was kept under observation for three years; he remained in excellent health and was never absent from work because of illness. In order to demonstrate conclusively that the nature of the haemoglobin caused no disadvantage, the red cell survival was determined after labelling his cells with chromium-51. The half-life was found to be 28 days (normal 24-34 days).

To elucidate further the nature of the non-sickling component in the haemoglobin, the haemolysate was examined by various electrophoretic methods on paper and starch, at varying pH, and by chromatography at pH 6 with 'IRC' resin<sup>1</sup>. A single band was always obtained.

\* Now at the Royal Infirmary, Manchester.

Fig. 1. Paper electrophoresis (tris buffer pH 8.9) of the propositus's haemoglobin, showing a single band in the position of Hb S

Fig. 2. Agar-gel electrophoresis (pH 6) of the propositus's haemoglobin, showing two bands, one in the position of Hb S and one in the position of Hb D

A haemoglobin which does not cause sickling, but is indistinguishable from Hb S by conventional methods of electrophoresis and by chromatography, is Hb D. This Hb separates, however, from Hb S on agar-gel electrophoresis at pH 6 (ref. 2). By this method the propositus's haemoglobin separated into two fractions, one in the position of Hb S and the other in the position of Hb A where among others Hb D would be expected to appear (Fig. 2). Contrary to the findings in sickle-cell Hb D disease neither Hb F was found, nor was the proportion of S greater than 50 per cent (on scanning it was found to be 20 per cent). The solubility according to Itano's test<sup>3</sup> was greater than that obtained in sickle-cell Hb D disease. It was in the upper range of that found in sickle-cell trait of the A + S type, namely, 180 mg/l. 2.24 M phosphate buffer.

Up to now we had considered the new haemoglobin to be D because it did not separate from Hb S on electrophoresis and on agar-gel electrophoresis was found to move like Hb D. It was still possible that its mobility was different from that of Hb S, but not sufficiently different to allow electrophoretic separation. To separate the non-sickling Hb from Hb S, 1 g of the propositus's haemoglobin dissolved in 40 ml. water was added to 160 ml. of 2.8 M phosphate buffer containing 2 g  $\text{Na}_2\text{S}_2\text{O}_4$ , mixed and incubated at 25° for 1 h. Insoluble haemoglobin was removed by centrifuging, and the supernatant haemoglobin solution was concentrated by dialysis *in vacuo*. The absence of Hb S could be demonstrated in a repeated Itano test when no precipitate was formed. A mixture of the isolated new haemoglobin with Hb A was compared with one of Hbs A + S by electrophoresis. The new haemoglobin had exactly the same mobility as Hb S (Fig. 3). Chromatography of the two mixtures on 'IRC 50' resin at pH 6 showed that Hb S and our new haemoglobin moved identically. Thus the non-sickling haemoglobin of our propositus was a true Hb D.

Fig. 3. Paper electrophoresis (tris buffer pH 8.9) of a mixture containing Hb A and the propositus's non-sickling Hb, and of Hbs A + S. The propositus's haemoglobin moves like Hb S, and thus is a Hb D

On electrophoresis at alkaline pH only Hbs S and D had been found in the propositus and in his mother. If the Hb D were an  $\alpha$ -chain abnormal variant, Hb A and a doubly abnormal hybrid moving more slowly than S + D would also have been expected. Thus our Hb D seemed to be a  $\beta$ -chain variant. This was confirmed by 'hybridization' of the isolated Hb D fraction with canine haemoglobin<sup>4,5</sup>. Mixtures of canine haemoglobin and Hbs A and D respectively were dissociated into their sub-units and these were then recombined. The electrophoretic mobility on starch at pH 8.2 of the  $\alpha_2$ human  $\beta_2$ canine hybrids was the same in both mixtures. The combination of the  $\alpha_2$ canine sub-unit with the  $\beta_2$  sub-unit of the HbD, however, moved more slowly than the  $\alpha_2$ canine  $\beta_2^A$  hybrid, indicating that the difference between the electrophoretic mobility of Hbs A and D was due to an increase in positive charge of the  $\beta$ -chains of the Hb D, that is, that the Hb D was a Hb D  $\beta$ .

To obtain more information on the chemical nature of this difference between Hb A and our Hb D  $\beta$ , 'fingerprints' of the purified Hb D were prepared. The haem was removed with acid/acetone<sup>6</sup>, and the globin digested with trypsin in 0.1 M  $\text{NH}_4\text{HCO}_3$  (pH 8.2) for 2 h at 38°. The pH was then adjusted to 6.4 with 0.5 M acetic acid and the insoluble 'core' was removed by centrifuging. After lyophilization of the supernatant, fingerprints were prepared by electrophoresis in a Michl type tank at pH 6.4 (ref. 7) using a potential gradient of 55 V/cm, followed by chromatography in iso-amyl alcohol/pyridine/water<sup>8</sup>. The peptides were rendered visible with 0.2 per cent ninhydrin in acetone, and submitted to the usual colour tests for specific amino-acids<sup>9-13</sup>. None of the peptides seen in fingerprints of Hb A was missing from the Hb D fingerprints. An additional peptide, however, was found just below  $\alpha\text{TpIII}$  (Fig. 4). The electrophoretic mobility

Fig. 4. Fingerprint of soluble tryptic peptides of Hb D Ibadan; 1, neutral peptides; 2, lysine ( $\alpha\text{TpVIII}$ ); 3,  $\alpha\text{TpIII}$ ; 4, new peptide

Fig. 5. Fingerprint of chymotryptic peptides of the Hb A core. The arrows indicate three peptides staining transiently yellow with ninhydrin. The right arrow also indicates the area of neutral peptides

Fig. 6. Fingerprint of chymotryptic peptides of the Hb D core. The arrows indicate two peptides staining transiently yellow with ninhydrin

at pH 6.4 was +0.49 (lysine = +1.0) and the  $R_F$  was 0.12 (25°). With ninhydrin it showed a transient yellow colour suggesting N-terminal glycyl. The specific colour tests for tyrosine<sup>9</sup>, tryptophan<sup>10</sup> and methionine<sup>11</sup> were negative, as were those for histidine<sup>12</sup> and arginine<sup>9,13</sup>.

As the peptide was a tryptic peptide its positive charge was presumably due to C-terminal lysyl, and its electrophoretic mobility suggested a sequence of four to five amino-acid residues. All the soluble tryptic peptides of Hb A were present, thus the additional peptide had to come from the usually insoluble core of the  $\beta$ -chain (residues  $\beta$ -83- $\beta$ -120).

The new peptide was isolated by paper electrophoresis at pH 6.4 and chromatography (24 h)<sup>8</sup>. The suspected presence of N-terminal glycyl was confirmed by a modified DNP method<sup>14</sup> and amino-acid analysis<sup>15</sup> demonstrated in equal amounts Thr, Gly, Phe and Lys (Table 1). The partial sequence could now be written as Gly-(Thr, Phe, Ala)-Lys. No glycine residue in the  $\beta$ -chain<sup>16,17</sup> has in its immediate sequence any combination of Thr, Phe, Ala except the Gly in position  $\beta$ -83, the N-terminal glycyl of the core peptide  $\beta$ TpX.

To determine the amino-acid sequence in the new peptide it was treated with chymotrypsin which hydrolyses phenylalanyl bonds. After digestion in 0.1 M  $\text{NH}_4\text{HCO}_3$  (pH 8.2) at 38° for 3 h, electrophoresis at pH 6.4 demonstrated two peptides. Their mobilities were +0.80 and 0 respectively (Table 2). The first was suggestive of the

dipeptide Ala-Lys for which at pH 6.5 a mobility of +0.77 had been reported<sup>14</sup>. Alanine was demonstrated to be its N-terminal residue, and hydrolysis of the peptide followed by high-voltage paper electrophoresis at pH 2.0 (ref. 18) showed only alanine and lysine to be present.

The neutral peptide showed a transient yellow colour with ninhydrin, indicating N-terminal glycyl, presumably the N-terminal residue of the original tryptic peptide. As in the original peptide the phenylalanyl bond was the only one easily susceptible to chymotryptic hydrolysis, Phe would be expected to be the C-terminal residue. This was confirmed by treatment of the peptide with carboxy peptidase-A which acts by splitting off the C-terminal residue. On high-voltage electrophoresis at pH 2 the amino-acid released was found to be phenylalanine.

The two chymotryptic peptides, therefore, had the sequences Gly-Thr-Phe and Ala-Lys, and the original peptide had to be Gly-Thr-Phe-Ala-Lys. From the known amino-acid sequences of Hb A (refs. 16 and 17) this peptide could correspond to the beginning of the core peptide  $\beta$ TpX Gly-Thr-Phe-Ala-Thr- ( $\beta$ -83- $\beta$ -87) if the threonine residue at position 87 of the  $\beta$ -chain of Hb A had been replaced by a lysine residue in Hb D  $\beta$ . As the residues 83-87 are the first five of the  $\beta$ -chain core a mutation of 87 Thr  $\rightarrow$  Lys would cause an additional soluble tryptic peptide to be found in the fingerprint of our Hb D  $\beta$ .

To confirm this origin of the additional D  $\beta$  peptide, fingerprints were prepared of the cores of Hb A and D  $\beta$ . The precipitates left after tryptic digestion were washed three times with Michl buffer pH 6.4 and then three times with water. They were then dissolved in 0.1 N hydrochloric acid precipitated with acetone and washed well with acetone by centrifuging. Chymotryptic digestion was carried out as described before, after which the pH was adjusted to 6.4 with acetic acid. A faint precipitate was centrifuged off and the supernatant was fingerprinted as described for the tryptic digest. The core fingerprint of Hb A (Fig. 5) showed three transiently yellow peptides when developed with ninhydrin, but that of the Hb D  $\beta$  core (Fig. 6) showed two. The additional 'yellow' peptide in the fingerprint of the Hb A core was in the neutral area. The neutral peptides of both cores were submitted to electrophoresis at pH 2. In each case several peptides separated, but one—transiently staining yellow with ninhydrin—was found only in the material from the Hb A core. Hydrolysis, followed by high-voltage electrophoresis at pH 2, showed the peptide to consist of glycine, threonine and phenylalanine. The peptide—missing in the core of Hb D—could only represent the first

Table 1. MOLAR RATIO OF AMINO-ACIDS AFTER ACID HYDROLYSIS OF TWO DIFFERENT PREPARATIONS OF THE ADDITIONAL PEPTIDE FROM Hb D

Threonine	0.9	1.0
Glycine (N-terminal)	1.0	1.0
Alanine	1.1	1.1
Phenylalanine	0.9	1.1
Lysine (C-terminal)	1.2	1.1

Table 2. AMINO-ACID ANALYSIS OF TWO CHYMOTRYPTIC PEPTIDES

	1	2
Mobility (Lys = +1.0)	+0.80	0
Threonine	+	+
Glycine (N-terminal)	—	+
Alanine (N-terminal)	+	—
Phenylalanine (C-terminal)	—	—
Lysine (C-terminal)	+	—

three residues of the  $\beta$ -chain core (83-85) of Hb A, and as this sequence of Hb D  $\beta$  was found in the soluble tryptic digest, it could not be expected to be present in the core of that Hb variant.

The formula of the Hb D  $\beta$  described here is therefore  $\alpha_2\beta_2^{87}\text{Thr} \rightarrow \text{Lys}$ , a new variant of Hb A: -D  $\beta$  Ibadan. It is the first example of a fully investigated mutation in the core, although another core mutation in Hb O Indonesia has been preliminarily reported as 116 Glu  $\rightarrow$  Lys (ref. 19). This is also the first mutation in which an additional polar group is introduced near the haem-linked histidine of human haemoglobin. No interference with the function of the haem was noted. Presumably the explanation is that this polar group—five residues away along the helical sequence—does not point in the direction of the ferrous atom.

It is of special interest that this haemoglobin is formed in preference to Hb S in the D + S heterozygote. D Ibadan seems to be as normal as Hb A, and its combination with Hb S does not result in sickle-cell Hb D disease. This preferential formation of a non-A haemoglobin in a sickle-cell heterozygote has only been reported once before—for a person with Hb J  $\beta$  Baltimore<sup>20</sup>. As more 'abnormal' haemoglobins are being examined, it is becoming quite certain that some of them are unusual rather than abnormal<sup>21</sup>.

Finally, Hb D Ibadan is the first example of a threonine  $\rightarrow$  lysine mutation in human haemoglobin. Recent investigations<sup>22</sup> of the triplet sequences of bases in RNA which determine the incorporation of amino-acids by a genetic code accept as the triplet code for lysine AAA

(A = adenine). The code suggested for threonine is AAC or ACA (C = cytosine), both of which would be compatible with a single mutation causing the step from threonine to lysine. Another proposed code for threonine, which lists in indeterminate order (ACC), would, however, not be compatible.

(Organic Chemistry Division)

Kettering-Meyer Laboratory\*, Southern Research Institute, Birmingham, Alabama

FOR a number of years basic biochemical and biological research has been directed toward gaining new knowledge regarding the mechanism of action of purine antagonists, particularly 6-mercaptopurine (MP) because of its useful temporary anti-leukaemic activity in man<sup>1</sup>. One of the goals of such efforts has been to gain information which could serve as a rationale for design and synthesis of purine antagonists that might circumvent the most prevalent biochemical mechanisms associated with cellular resistance to MP.

A common biochemical alteration (observed in bacteria, experimental cancer cells including leukaemic cells, and human cancer cells in culture) associated with the development of cellular resistance to MP is the loss of activity of a specific nucleotide pyrophosphorylase (IMP-GMP pyrophosphorylase) responsible for catalysing the conversion of MP to its cytotoxic form, MP-ribonucleotide<sup>2</sup>. It

has not been possible to circumvent this loss of pyrophosphorylase activity by exposure of MP-resistant cells to MP-ribonucleotide, because this nucleotide either fails to enter the cell, or is degraded in the process of entry. MP-ribonucleotide is also ineffective against MP-resistant cells; its inactivity may be due either to its rapid degradation to MP (which has been observed in Ehrlich ascites cells<sup>3</sup>), to the absence of the necessary nucleoside phosphokinase activity (presumably 'inosine kinase', an enzyme which has not been reported<sup>4</sup>), or to both these factors. Efforts to overcome resistance to MP by employment of bis(thioinosine)-5',5'''-phosphate have shown some promise<sup>5</sup>, but MP-resistant cells in culture show some degree of cross-resistance to this compound (about 20- to 40-fold as compared with >1,000-fold resistance to MP). Such cross-resistance is too great to offer encouragement for *in vivo* activity against MP-resistant neoplasms, because of the relatively low therapeutic index of all known purine antagonists.

Table 1. RELATIVE EFFECTIVENESS OF 6-METHYLTHIOPURINE RIBONUCLEOSIDE AND RELATED COMPOUNDS AGAINST *H. Ep. No. 2* CELLS IN CULTURE AND A 6-MERCAPTOPYRINE-RESISTANT VARIANT

Compound	Average $ED_{50}$ ( $\mu\text{g/ml.}$ )*	
	<i>H. Ep. No. 2/S</i>	<i>H. Ep. No. 2/MP</i>
6-Mercaptopurine	0.21	400
6-Mercaptopurine ribonucleoside	0.36	>100
6-Mercaptopurine ribonucleotide	0.61	>100
6-Methylthiopurine	73	111
6-Methylthiopurine ribonucleoside†	0.10	0.07
6-Methylthiopurine ribonucleotide†	0.17	0.04
6-Ethylthiopurine ribonucleoside	0.29	0.29
6-Benzylthiopurine ribonucleoside	3.7	2.8
6-Cyclopentylthiopurine ribonucleoside	>100	>100
6-Thioguanine	0.04	52
6-Thioguanosine	0.38	>100
6-Thioguanic acid	0.28	>100
6-Methylthioguanine	44	32
6-Methylthioguanosine	>100	>100

\*  $ED_{50}$  is that concentration of drug inhibiting cell growth by 50 per cent. Cells were grown on glass and growth was measured by determination of protein content (method of Oyama and Eagle (ref. 30)) after 4 days growth in the presence of drug.

† Average of 9 independent and internally consistent experiments.

‡ Barium salt monohydrate.

The present article is concerned with the biological activity (including the *in vivo* anti-leukaemic activity), some intermediary metabolic effects, and the metabolism of 6-methylthiopurine ribonucleoside (MeMP-ribonucleoside), a simple derivative of MP with high activity in culture against human cancer cells resistant to MP.

**Inhibition studies with *H. Ep. No. 2* cells in culture.** The isolation of a line of human epidermoid cancer cells (*H. Ep. No. 2*) resistant to MP has already been described<sup>6</sup>; this line is completely devoid of IMP-GMP pyrophosphorylase, which converts MP to MP-ribonucleotide<sup>7</sup>. A second line of *H. Ep. No. 2* cells resistant to MP was also used in studies of metabolic effects described later; this line shows the same loss of IMP-GMP pyrophosphorylase activity as the first MP-resistant line, but since it represents an independently isolated cell line and since it has been carried in the presence of 6-thioguanine rather than MP, it is given a separate designation (*H. Ep. No. 2/MP/TG*) to distinguish it from the first resistant line (*H. Ep. No. 2/MP*) and the parent line (*H. Ep. No. 2/S*). These cell culture lines were propagated in stationary culture in Eagle's basal medium supplemented with 10 per cent calf serum. The drug response was quantitatively assessed by a standardized procedure<sup>8</sup>. The results, presented in Table 1, show the inability of MP, MP-ribonucleoside and MP-ribonucleotide to inhibit the resistant line, and also show the cross-resistance of this line to 6-thioguanine,

6-thioguanosine, and 6-thioguanic acid. In contrast, MeMP-ribonucleoside was equally effective against *H. Ep. No. 2/S* and *H. Ep. No. 2/MP* cells, as were MeMP-ribonucleotide and the *S*-ethyl and *S*-benzyl (but not the *S*-cyclopentyl) derivatives of MP-ribonucleoside. The free base, 6-methylthiopurine (MeMP), was relatively non-toxic to both the sensitive and resistant lines, the  $ED_{50}$  concentrations being 700- to 1,000-fold higher than those of MeMP-ribonucleoside. It is also of interest that a similar relationship did not hold in the thioguanine series: both 6-methylthioguanine and 6-methylthioguanosine were relatively without inhibitory activity against both MP-sensitive and MP-resistant cell lines.

**Evaluation of the response in vivo of L1210 leukaemia and an MP-resistant variant thereof to MeMP-ribonucleoside.** Using standardized procedures<sup>9</sup>, MeMP-ribonucleoside and MP have been compared with regard to capacity to increase life-span of *BDF<sub>1</sub>* mice bearing L1210 or L1210/MP leukaemias. The design and results of these experiments are shown in Table 2. MeMP-ribonucleoside was about as effective against the MP-resistant leukaemia as was MP against the parent sensitive leukaemia, and MeMP-ribonucleoside produced about the same increase in life-span in mice with sensitive and with MP-resistant leukaemic cells. These results have been confirmed repeatedly.

**Pseudo-feedback inhibition of purine biosynthesis.** Many purine analogues, including MP, inhibit an early step of purine biosynthesis<sup>10-13</sup> presumably the first step of the pathway<sup>14</sup>, as a result of the capacity of their nucleotides to mimic the action of natural purine nucleotides as feedback inhibitors. Earlier investigations with MP and other purine analogues in resistant cells have shown that pseudo-feedback inhibition of purine biosynthesis occurs only in cells that have the capacity to form the nucleotides<sup>13,15</sup>. Since the activity of MeMP-ribonucleoside against MP-resistant cells suggests that MeMP-ribonucleoside is being converted to a nucleotide in cells where such conversion of MP or MP-ribonucleoside does not occur, it was of interest to determine the effectiveness of this compound as a pseudo-feedback type of inhibitor.

Azaserine specifically blocks an early step in purine biosynthesis, and the feedback or pseudo-feedback inhibition can be assayed conveniently by determining the effectiveness of a given agent in decreasing the amount of <sup>14</sup>C-labelled formylglycinamide ribonucleotide (FGAR)

Table 2. A COMPARISON OF THE *in vivo* RESPONSE OF 6-MERCAPTOPYRINE-RESISTANT L1210 LEUKAEMIA TO 6-METHYLTHIOPURINE RIBONUCLEOSIDE AND 6-MERCAPTOPYRINE\*

No. of L1210/MP cells inoculated	Treatment	Dosage (qd 1-15 days)			Median host life-span (days)		% Increase in host life-span†

		5	15	0.33		18.0	50

\* The above are results from concurrent experiments in which randomly distributed leukaemic mice were used. Leukaemic cells were inoculated intraperitoneally and all therapy was by the intraperitoneal route. The MP-resistant leukaemia used was a line (L1210/MP (III)) isolated by Hutchison (ref. 31). The maximum percentage increase in host life-span of animals bearing L1210/MP leukaemia provided by MeMP-ribonucleoside is approximately the same as that observed in animals bearing the parent L1210 leukaemia on treatment with the optimal chronic dosage of MP (ref. 32). In experiments carried out so far, the activity of MeMP-ribonucleoside and MP against the parent line of L1210 leukaemia appear to be about the same.

† Groups of 20 control and 10 treated animals were used. There were no 30-day survivors in either control or treated groups.

that accumulates in cells provided  $^{14}\text{C}$ -formate and treated with azaserine. The procedures used, which have been described in detail elsewhere<sup>13,15,16</sup>, are modifications of those used by LePage, Henderson *et al.*<sup>11,12</sup>. The details of the experiments are contained in Table 3, which presents the results obtained with the two separate MP-resistant *H. Ep.* No. 2 lines and the parent sensitive line in culture and with L1210/MP cells *in vivo*. Each of these resistant cell lines previously has been shown to be cross-resistant to MP-ribonucleoside and to be devoid of IMP-GMP pyrophosphorylase activity, the enzyme which converts MP and 6-thioguanine to nucleotides<sup>7,13</sup>.

\* Cells were treated with azaserine (10  $\mu\text{g/ml.}$ ), and sodium formate- $^{14}\text{C}$  (25  $\mu\text{C.}$  per flask or bottle) was added 1 h later. Purine analogues were added 30 min after the azaserine. Controls (azaserine control) received only azaserine and formate- $^{14}\text{C}$ . Cells were collected 2 h after addition of the radioactive formate.

† Azaserine (0.5 mg/kg) was administered intraperitoneally to groups of 3 mice each, bearing 7-day-old implants of leukaemia L1210/MP (ref. 31), followed 30 min thereafter by the purine analogue. Sodium formate- $^{14}\text{C}$  (50  $\mu\text{C.}$ /mouse) was given 1 h after the azaserine, and the cells were collected 2 h after administration of the tracer. The soluble fraction of the cells was prepared and assayed by the same methods used for *H. Ep.* No. 2 cells.

MeMP-ribonucleoside at concentrations of 0.5  $\mu\text{g/ml.}$  or less blocked the formation of FGAR almost completely in both the sensitive and resistant cell culture lines. MP-ribonucleoside was effective in blocking FGAR synthesis in *H. Ep.* No. 2/S cells, but not in *H. Ep.* No. 2/MP or *H. Ep.* No. 2/MP/TG cells. MP was also without effect on FGAR synthesis in the *H. Ep.* No. 2/MP/TG line; its high effectiveness in the parent line and its ineffectiveness in the *H. Ep.* No. 2/MP line have been reported earlier<sup>13</sup>. MeMP-ribonucleoside, at therapeutic doses, was also highly effective in blocking synthesis of FGAR in L1210/MP leukaemic cells *in vivo*, whereas MP-ribonucleoside was without effect (Table 3). The effectiveness of MeMP-ribonucleoside as a pseudo-feedback inhibitor has also been noted by Henderson<sup>12</sup> in studies with Ehrlich ascites cells *in vitro*.

**Metabolism of MeMP-ribonucleoside- $^{35}\text{S}$ .** MP-ribonucleoside- $^{35}\text{S}$  was prepared by exchange between sulphur-35 dissolved in pyridine and unlabelled MP-ribonucleoside as described by Moravsek and Nejedly<sup>17</sup>. Methylation of MP-ribonucleoside- $^{35}\text{S}$  with methyl iodide gave MeMP-ribonucleoside- $^{35}\text{S}$ , obtained in about 80 per cent overall yield from sulphur-35. Two batches of labelled compound with specific activities of 2.6  $\mu\text{C.}/\text{mg}$  and 16.5  $\mu\text{C.}/\text{mg}$  were used in metabolism studies. *H. Ep.* No.

2/S and *H. Ep.* No. 2/MP/TG cells in suspension culture ( $4-6 \times 10^7$  cells in 200 ml. medium) were exposed to MeMP-ribonucleoside- $^{35}\text{S}$  (5  $\mu\text{g/ml.}$ ) for 4 h. At this time, the cells were collected by centrifugation, washed, and extracted with hot 80 per cent ethanol as described elsewhere<sup>16</sup>. Three to four per cent of sulphur-35 added was present in the ethanol extract. The alcohol extract was analysed by two-dimensional paper chromatography-autoradiography (phenol-water followed by *n*-butanol-propionic acid-water) and by one-dimensional paper chromatography (butanol-propionic acid-water), as described previously<sup>16</sup>. Eighty to eighty-five per cent of the total sulphur-35 on the chromatograms was located in a spot falling in the nucleotide area of the chromatograms ( $R_F$  0.30 in butanol-propionic acid); 5-11 per cent of the total sulphur-35 was in a spot of  $R_F$  0.71, and the remainder in several small spots falling below the principal spot. Similar uptake and distribution were observed in both cell lines, and 24 h exposure to the labelled drug did not change either the extent of uptake or the distribution of radioactivity among the spots on the chromatogram. By co-chromatography in three solvents the spot with  $R_F$  value 0.71 was identified as unchanged MeMP-ribonucleoside. The principal spot ( $R_F$  0.30) was identified as the 5'-mono-phosphate of MeMP-ribonucleoside by (a) co-chromatography with an authentic synthetic sample of 6-methylthioinosine-5'-phosphate (prepared by the methylation of thioinosinic acid (J. A. Montgomery and H. J. Thomas, unpublished observations)), in three solvents (butanol-propionic acid-water; dicyclohexylamine, butanone,  $\text{H}_2\text{O}$  (2:10:5, v/v); *t*-butyl alcohol, butanone,  $\text{H}_2\text{O}$ , diethylamine (4:4:2:4, v/v)), in all of which there was complete coincidence of ultra-violet absorption and radioactivity; and (b) by treatment with calf intestinal phosphatase (Pentex, Inc., Kanakee, Ill.) for 1.5 h, 37° C, pH 9-10, which converted the principal spot completely to a compound indistinguishable from MeMP-ribonucleoside by co-chromatography. The identities of the spots with  $R_F$  values less than that of the nucleoside monophosphate have not been determined. MeMP has been observed to undergo some demethylation *in vivo* and *in vitro*<sup>18-20</sup>; MP-ribonucleotide was therefore a probable metabolite of MeMP-ribonucleotide. However, in the butanol-propionic acid solvent, MP-ribonucleotide ( $R_F$  0.09-0.13) and MeMP-ribonucleotide can be distinguished easily; very little radioactivity at the  $R_F$  of MP-ribonucleotide was noted on chromatography-autoradiography of extracts of cells exposed to MeMP-ribonucleoside- $^{35}\text{S}$ ; and when the material falling at this  $R_F$  value was eluted and treated with alkaline phosphatase, no radioactivity was detected at the  $R_F$  of MP-ribonucleoside. There was, therefore, little or no conversion of MeMP-ribonucleoside to MP-ribonucleotide.

The possible incorporation of MeMP-ribonucleoside into polynucleotides is a question yet unanswered. When *H. Ep.* No. 2/S cells were grown in the presence of MeMP-ribonucleoside- $^{35}\text{S}$ , very small amounts of radioactivity were isolated with the nucleic acids. Determination of whether this radioactivity represents only contamination or a true incorporation is made difficult by the very small amount of sulphur-35 isolated with the polynucleotides and by the instability of MeMP-ribonucleotide—an instability which we observed in the present work and which has recently been noted also by Pfeleiderer *et al.*<sup>21</sup>. Additional evidence against incorporation into polynucleotides is the fact that on chromatograms made from the 80 per cent alcohol extracts of cells grown in the presence of MeMP-ribonucleoside- $^{35}\text{S}$  there was little radioactivity in the area to which the di- and tri-phosphates of MeMP-ribonucleoside would be expected to migrate.

It is also worth noting that no MeMP was detected on the chromatograms made from the 80 per cent alcohol extracts—results indicating that MeMP-ribonucleoside is not degraded by nucleoside phosphorylases in intact cells.

This finding is in accord with the recent report of Paterson and Sutherland<sup>3</sup> that MeMP-ribonucleoside is not converted to MeMP by cell-free extracts of Ehrlich ascites cells.

In separate experiments, cell-free extracts of *H. Ep.* No. 2/S cells were incubated for varying lengths of time with MeMP-ribonucleoside-<sup>35</sup>S (in *tris* buffer, 0.05 M, pH 7.4, containing ATP at a final concentration of 3.1  $\mu$ moles/ml.), after which the incubation mixtures were analysed by the usual chromatography-autoradiography procedures. The autoradiographic patterns thus obtained were similar to those obtained in intact cells; MeMP-ribonucleoside was the principal spot, and the maximum amount of nucleotide was produced during the first 20 min of incubation.

The various types of data presented here show MeMP-ribonucleoside to be an interesting compound on several counts. From the practical point of view, it is a simple derivative of MP that overcomes a mechanism of resistance to MP that is found in many species. From the biochemical point of view, it is of interest that *S*-methylation of MP-ribonucleoside apparently completely changes its substrate specificity for some of the enzymes of purine metabolism. Thus, in intact cells MeMP-ribonucleoside would appear not to be a substrate for nucleoside phosphorylases, and, *in vitro*, MeMP-ribonucleoside remains intact under conditions that produce extensive cleavage of MP-ribonucleoside to the free base<sup>8</sup>. The extensive conversion of MeMP-ribonucleoside to the nucleotide in cells which fail to convert MP-ribonucleoside to the nucleotide shows MeMP-ribonucleoside to be a substrate for a nucleoside kinase that does not act on MP-ribonucleoside. Kinases for inosine and guanosine have not been reported<sup>4</sup>, whereas adenosine kinase is known to occur in mammalian cells<sup>22</sup>; other ribonucleoside kinases known are uridine kinase, riboflavin kinase, and ribosyl-nicotinamide kinase<sup>22</sup>. These facts, and the fact that MeMP-ribonucleoside acts as a purine analogue in inhibiting purine synthesis by a pseudo-feedback action, make it likely that it is adenosine kinase that converts MeMP-ribonucleoside to the nucleotide. With regard to the possibility that MeMP-ribonucleoside is an analogue of adenosine, it is worth noting that, whereas inosine (I) and MP-ribonucleoside (II) both bear a proton at N-1 (since they exist largely in the lactam and thiolactam forms<sup>23</sup>), adenosine (III)<sup>24,25</sup> and MeMP-ribonucleoside (IV) do not. The absence of a proton at N-1 of the pyrimidine ring might, therefore, be more critical for activity as a substrate for the kinase than the nature of the group at the 6-position of the ring. In this connexion,

the inhibitory activity of other *S*-substituted derivatives of MP-ribonucleoside should be noted (Table 1). Another interesting point relating to substrate specificity is the fact that MeMP was not a substrate for any of the purine nucleotide pyrophosphorylases when assays were carried out with cell-free extracts of *H. Ep.* No. 2/S cells by procedures that have been described elsewhere<sup>7,26</sup>. This finding would suggest that the activity of MeMP *in vivo*<sup>27,28</sup>

is the result of demethylation to MP and its consequent conversion to the nucleotide by sensitive cells.

In so far as its metabolism in cultured cells is concerned, MeMP-ribonucleoside (and possibly its congeners) appears, then, to be a unique inhibitor in that it is not a substrate for enzymes degrading other purine nucleosides but is an excellent substrate for a kinase that converts it to the nucleotide, apparently the active inhibitory form. Since MeMP-ribonucleoside is converted to MeMP-ribonucleotide and not to 6-MP-ribonucleotide, it is an interesting question whether these two nucleotides inhibit cell division by means of the same mechanism. All facets of the action of MP are not yet understood; however, with regard to the mechanisms of action of MP and MeMP-ribonucleoside and to the possibility that MeMP-ribonucleoside acts as an adenosine analogue, it is noteworthy that both MP and MeMP-ribonucleoside (after intracellular conversion to the nucleotide) are potent pseudo-feedback inhibitors of purine biosynthesis in intact mammalian cells, and that this is an action that they have in common with several cytotoxic analogues of adenosine and adenosine, that is, 2-fluoroadenosine, 2-fluoroadenosine, 7-deazaadenosine (tubercidin), and others<sup>29</sup>.

The *in vivo* activity of MeMP-ribonucleoside against leukaemia L1210/MP suggests that this agent is worth considering for clinical trial against MP-resistant acute lymphatic and chronic myelocytic leukaemias.

## INHIBITORY EFFECT OF *p*-BENZOQUINONE ON THE AGGREGATION BEHAVIOUR OF EMBRYO-CHICK FIBROBLAST CELLS

By PROF. BRYN M. JONES

Department of Zoology, University College of Wales, Aberystwyth

IT has long been recognized that the adhesion and de-adhesion of cells in association with their movements from one place to another in an organism is a biological phenomenon of considerable importance. It lies at the root of such problems as embryogenesis, wound healing, and certain abnormal growth conditions. There is now abundant evidence that tumour cells, at least *in vitro*, are less adhesive than their normal counterparts<sup>1</sup>.

I have previously advanced the hypothesis that cellular adhesiveness is an expression of the degree of integration of the molecular complex (by cross-linkage) at the cell surface<sup>2</sup>. It was partly derived from the observation that quinone-tanned membranes, which have a relatively high surface viscosity due to bonding and contraction, are less adhesive than untanned ones<sup>2</sup>. Investigations on the reactions between a collagen monolayer and a tanning agent have shown that they are characterized by a considerable increase in surface viscosity together with increases in surface pressure and surface potential. It is considered that these particular changes are the result of cross-linking produced by tanning agents<sup>3</sup>. It is also likely that contraction of a cell surface after treatment with a tanning agent would be accompanied by an increase in the surface density charge.

A high surface viscosity, surface potential and surface density charge are regarded as being unfavourable to cellular adhesiveness<sup>4</sup>. It is significant that these properties are acquired by tumour cells, which seem to have relatively rigid surfaces and a high overall electronegative charge<sup>5</sup>. It has been suggested<sup>6</sup> that some form of discontinuous tanning of a cell surface, such as occurs when erythrocyte membranes are treated with tannate ions<sup>6</sup>, could increase surface rigidity without hindering pseudopod formation or pinocytosis.

It is legitimate to assume, therefore, that if the surfaces of cells were treated with a tanning agent, their adhesiveness would be reduced. Whether this could occur naturally is another question. But among the agents likely to bring this about are vitamin K<sub>1</sub> (2-methyl-3-phytyl-1,4-naphthoquinone), the ubiquinones, and their derivatives. It is interesting that the sensitivity of cells to radiation damage is relatively lower after treatment with menadione or synthetic vitamin K (2-methyl-1,4-naphthoquinone). It has been suggested that this compound tanned the surfaces of the cells to provide a charge distribution required for repairing the small radiation-induced lesions<sup>7</sup>. This effect recalls how the electrophoretic mobility of the cells of *Aerobacter aerogenes* is increased after treatment with phenols<sup>8</sup>. According to the investigators, the phenol caused a contraction of the cell surfaces, thereby raising the surface density charge.

It therefore seemed that the adhesiveness of cells would be reduced after treatment with a tanning agent, and this suggested an examination of the effect of *p*-benzoquinone on the aggregating ability of embryo-chick fibroblast cells.

The cells were derived from the muscle tissues of 10-day-old chick embryos. These were removed from the eggs under aseptic conditions, and the muscle tissues were washed thoroughly in warm Hanks's solution before being dissociated into free cells in a 1 per cent trypsin (Difco 1:250) solution for 10–15 min at 37° C. The cells were washed and re-suspended in Hanks's solution.

When the cells were treated with *p*-benzoquinone dissolved in Hanks's solution, it was found that the cells could tolerate exposure to concentrations not exceeding 10<sup>-6</sup> M for 10 min (ref. 9). Cell viability was little impaired after treatment with the quinone compound at concentrations within the range of 10<sup>-6</sup> M–5 × 10<sup>-6</sup> M. When the treated cells were re-suspended in a culture medium consisting of 10 per cent calf serum in Hanks's solution, only about 10 per cent of the cells showed an affinity for eosin stain after they had been in the medium for 5 h. Treated cells also proliferated in culture, although the length of the initial lag phase in cell growth was proportional to the concentration of *p*-benzoquinone to which the cells had previously been exposed. When the cells had been treated with *p*-benzoquinone at 10<sup>-6</sup> M or 2 × 10<sup>-6</sup> M they proliferated in culture as readily as untreated cells. Accordingly, it was decided to test the effect of *p*-benzoquinone at concentrations ranging from 10<sup>-6</sup> to 5 × 10<sup>-6</sup> M, which were non-lethal, on the adhesiveness of the cells.

Experiments designed to test the effect of chemical and physical factors on the aggregating capacity of cells in suspension have recently been initiated<sup>10</sup>. They have been based on the principle of bringing cells into contact with each other by gently swirling at about 70 r.p.m. in solutions contained in flasks inserted in a gyratory shaker. In the present investigation, 2-ml. samples of cell suspensions in siliconized test-tubes were placed in absorptiometers (E.E.L. 'Quantitrator' with 'Univalvo 20' attached), and stirred with a magnetically rotated rod covered with siliconized glass at 37° C. Optical density was continuously recorded at a wave-length of 600 mμ. A decrease in optical density occurs when the cells aggregate and an increase if cell aggregates disperse. This turbidimetric method is the same as that which has been successfully used in studies on platelet clumping<sup>11</sup>.

The fibroblast cells, after trypsinization, were re-suspended in Hanks's solution. The cell density was adjusted to 10 million cells/ml. by using a haemocytometer, and the cell preparation was divided into four aliquots. The cells of three of them were re-suspended for 10 min in Hanks's solution containing concentrations of *p*-benzoquinone at 10<sup>-6</sup> M, 2 × 10<sup>-6</sup> M, and 5 × 10<sup>-6</sup> M respectively. The cells of each of these samples were washed in Hanks's solution and re-suspended in a medium composed of 10 per cent calf serum in Hanks's solution. The untreated cells of the remaining sample were also re-suspended in this medium. Each of the four cell preparations was placed in an absorptiometer, the tube being inserted in a water-heated 'Perspex' holder fixed to the test platform. In each experiment changes in optical density in the three treated and one untreated cell preparations were recorded over a period of about 5 h, or until the process of cell aggregation had come to an end.

Fig. 1 shows that in both the control and treated cell preparations there was a significant increase in optical density in the first half-hour. Thereafter, it will be seen from the slopes of the curves that in both the treated and untreated preparations the optical density gradually decreased. The overall decrease in optical density is inversely proportional to the concentration of *p*-benzoquinone. The length of the first downward inflexion in

Fig. 1. Effect of pretreating embryo-chick fibroblast cells with *p*-benzoquinone on the optical density of a suspension of  $12 \times 10^5$  cells/ml. in a rotating medium. The curves are related to the following concentrations of *p*-benzoquinone: A, nil (control); B,  $10^{-6}$  M; C,  $2 \times 10^{-6}$  M; D,  $5 \times 10^{-6}$  M.

the curves is also related to the concentration of the quinone. This inflexion in the curves, however, is interrupted by a less steep slope in the 2nd hour. In the 3rd hour each curve flattens out. In the case of the preparations in which the cells were previously treated or tanned with *p*-benzoquinone at a concentration of  $5 \times 10^{-6}$  M (curve D), the rate of decrease in optical density was relatively slow, and there was no further decrease after 2 h. When the cells had been previously treated with *p*-benzoquinone at a concentration of  $2 \times 10^{-6}$  M (curve C), the pattern was similar except that the decrease in optical density was relatively more rapid before it ended after 2.5 h, as signified by the plateau. The plateau in curve B is a small one, reflecting a short delay in the decrease in optical density. The plateau in the control curve A was equally small, but it was followed by a steep inflexion in the 4th hour. In control preparations in particular, the process of cell aggregation was liable to continue for up to about 5 h. The pattern of these results (Fig. 1) was qualitatively reproducible. It is also of interest that the same pattern of results was obtained in Hanks's solution<sup>9</sup>.

When samples of the cell preparations were examined from time to time during an experiment, it became apparent that cell aggregates were formed within the first hour. These initial cell aggregates increased in size in the next 1.5 h. In the control preparations in particular, it was evident that in the last 1- to 2-h period of the experiment, the aggregates already formed tended to adhere to each other to produce larger ones. Relatively few fibroblast cells remained in the control preparations after cell aggregation had come to an end (Fig. 2A). In the treated cell preparations more cells remained free, particularly in the preparation in which they had been treated with *p*-benzoquinone at the highest concentration ( $5 \times 10^{-6}$  M, Fig. 2B). Eosin staining of the remaining free cells revealed that 85-90 per cent of them were viable.

The failure of these viable cells to take part in the formation of aggregates in the treated cell preparations was responsible for the relatively slighter overall decrease in optical density in these preparations. Treatment of the cells with *p*-benzoquinone, therefore, had antagonized their capacity to aggregate without impairing their viability. The adhesiveness of the cells had presumably been reduced by the tanning action of the *p*-benzoquinone molecules adsorbed at the surfaces of the cells. This is probable, because when exogenous quinones succeed in entering cells the effect is lethal, owing to the formation of hydrogen peroxide during antioxygenation of hydroquinones within the cell<sup>12</sup>.

How quinone molecules adsorbed at the surfaces of cells could inhibit cell aggregation is less easy to explain, because we have no clear understanding of the nature of the adhesive mechanisms at the surfaces of cells, or what alterations to the surface properties render cells less 'sticky'. The present findings suggest that a tanning reaction between *p*-benzoquinone and components (probably protein) at the surfaces of the cells is responsible for reducing cellular adhesiveness by increasing the surface viscosity. The same tanning reaction could also cause contraction at the cell surface and an accompanying increase in the surface density charge, an effect which is thought to occur when cells of *A. aerogenes* are treated with phenols<sup>3</sup>. In addition, quinones at the surfaces of cells would probably be reduced to quinols bearing negative groups, which would increase the overall electro-negative surface charge. All these changes, which can be brought about by the reaction of *p*-benzoquinone with

Fig. 2. Effect of pretreating embryo-chick fibroblast cells with *p*-benzoquinone on their aggregation in a rotating medium. A, Aggregates of untreated cells; B, aggregates of cells pretreated with *p*-benzoquinone at  $2 \times 10^{-6}$  M (note the relatively large number of free cells which had failed to take part in the formation of aggregates).

the surfaces of cells, are recognized as being unfavourable to cell adhesion<sup>4</sup>, and they provide an explanation for the inhibitory effect of *p*-benzoquinone on the aggregating ability of the embryo-chick fibroblast cells in the present experiments. The findings are also in line with the view, which formed a basis for this work, that cellular adhesiveness partly depends on the degree of integration (by cross-linking) of macromolecules at the cell surface<sup>5</sup>.

I thank Miss I. Cunningham for her help particularly in standardizing the methods adopted. I also thank Mrs. Howse and Mr. Hirst for their help in this work, which was aided by grants provided by the British Empire Cancer Campaign for Research and the Department of Scientific and Industrial Research.

## SELECTIVE AND MUTUAL SENSITIZATION OF DELAYED FLUORESCENCE

By DR. C. A. PARKER, C. G. HATCHARD and THELMA A. JOYCE

Royal Naval Scientific Service, Admiralty Materials Laboratory, Holton Heath, Poole, Dorset

THE process of triplet energy transfer to a singlet molecule in the ground state, as represented by the equation:

has been investigated in solution by flash excited phosphorescence measurement<sup>1-3</sup>, by flash absorption spectroscopy<sup>4</sup>, and by quenching or sensitization of photochemical reactions<sup>1,5</sup>. For a limited number of systems it has been found that, if the triplet level of the acceptor lies well below that of the donor, the transfer rate is diffusion-controlled, but if it lies well above that of the donor, energy transfer is negligible. If the values of the triplet energies are nearly equal, Bäckström and Sandros<sup>3</sup> concluded that process (1) is reversible. The ratio of the rates of the forward and back reactions should then be equal to  $\exp(\Delta E/RT)$  (where  $\Delta E$  is the difference of the two triplet energies) and the apparent transfer efficiency should be less than that for a diffusion-controlled reaction, and should be temperature-dependent.

Another method for the investigation of process (1) is suggested by the discovery that triplet energy can be transferred to a second triplet molecule. This leads to the formation of an excited singlet molecule and is responsible for the production of sensitized *P*-type delayed fluorescence<sup>6-8</sup>. By using as donor a molecule the excited singlet level of which is lower than that of the acceptor, the triplet level of the latter can be populated by light absorbed only by the donor, and the resulting sensitized anti-Stokes delayed fluorescence<sup>9</sup> can in principle provide a sensitive indication of the occurrence of process (1). We present here some preliminary results obtained with this technique, using three dyestuffs as donors and various aromatic hydrocarbons as acceptors.

### Selective Sensitization

The ratio of the delayed fluorescence efficiencies,  $\theta_A$ , to the prompt fluorescence efficiencies,  $\phi_A$ , of the acceptors at a concentration of  $10^{-6}$  M in ethanol at 22°C is shown in Table 1. At this temperature the lifetimes of the donor triplets, as indicated by the lifetimes of their *E*-type delayed fluorescence<sup>9</sup>, were of the order 5 msec for proflavine and acridine orange hydrochlorides and 2 msec for eosin di-sodium salt. Thus, if quenching is diffusion-controlled ( $k_T = 0.57 \times 10^{10}$  l. mole<sup>-1</sup> sec<sup>-1</sup> at 22°C), the donor triplets should be more than 90 per cent quenched at acceptor concentrations of  $10^{-6}$  M. At this concentration, therefore, the delayed fluorescence efficiency of the

acceptors should be high, low or zero according to whether their triplet levels lie well below, near, or well above those of the donors. The values of  $\theta_A/\phi_A$  in Table 1 are generally in agreement with this prediction, although the results for perylene with proflavine and acridine orange hydrochlorides are lower than would be expected.

Table 1. SELECTIVE SENSITIZATION OF DELAYED FLUORESCENCE AT 22°C

Compound	Triplet level $\mu\text{m}^{-1}$	$10^3 \theta_A/\phi_A$ with sensitization by:		
		Proflavine hydrochloride	Acridine O hydrochloride	Eosin di-sodium salt
Naphthalene	2.12 <sup>2</sup>	<0.01	<0.01	<0.01
Proflavine (donor)	1.71*	—	—	—
Pyrene	1.69 <sup>3</sup>	0.03	<0.01	<0.01
1:2-benzanthracene	1.65*	0.5	<0.01	<0.01
Acridine O (donor)	1.60*	—	—	—
Anthracene	1.48*	0.7	1	0.01
3:4-benzpyrene	1.47 <sup>10</sup>	2	1	0.06
Eosin (donor)	1.42*	—	—	—
Perylene	1.26 <sup>11</sup>	0.1	0.2	0.7

Rates of light absorption by donors were approximately  $6 \times 10^{-4}$ ,  $6 \times 10^{-4}$  and  $1 \times 10^{-5}$  einstein l.<sup>-1</sup> sec<sup>-1</sup> at 436, 436 and 546 nm for proflavine, acridine O and eosin. Acceptor concentrations were all  $10^{-6}$  M.

\* These values calculated from the maxima of the *T*→*S* emission spectra at -75°C.

At -75°C the diffusion-controlled rate constant ( $k_T$ ) in ethanol is 20 times smaller, while the lifetimes of the triplets of proflavine and acridine orange hydrochlorides are some 20 times greater than at 22°C. Thus, with an acceptor concentration of  $10^{-6}$  M, the delayed fluorescence efficiencies should show a variation qualitatively similar to that at 22°C, at least for those systems where the triplet levels of donor and acceptor are well separated. The results in Table 2 (with the exception of those for perylene) bear this out. Perylene is sparingly soluble in ethanol at room temperature and it is possible that at low temperature most of the perylene had crystallized from solution.

It is of particular interest to compare the efficiencies for those systems where the donor and acceptor triplets lie close together. Examples of two types are illustrated in Tables 1 and 2.

*Type 1. Acceptor triplet just below that of donor.* The efficiency of the proflavine-sensitized delayed fluorescence of pyrene at 22°C is much less than that of benzantracene (Table 1, column 3), as would be expected if reaction (1) were reversible. At -75°C the reverse rate of reaction (1) should be reduced and, as indicated in column 3 of Table 2,  $\theta_A/\phi_A$  is indeed greater in comparison with the value for benzantracene (see Fig. 1). It is increased still further by the presence of a greater concentration of pyrene (column 4 of Table 2).

*Type 2. Acceptor triplet just above that of donor.* At a concentration of  $10^{-6}$  M neither pyrene nor benzantracene

Fig. 1. Mutual sensitization of delayed fluorescence with proflavine hydrochloride as donor. Delayed emission spectra of  $8 \times 10^{-3}$  M proflavine hydrochloride in ethanol at  $-75^\circ\text{C}$  with (1) no addition; (2)  $10^{-4}$  M anthracene; (3)  $10^{-6}$  M 1:2-benzanthracene; (4)  $10^{-4}$  M pyrene. Rate of light absorption was  $6 \times 10^{-6}$  einstein  $\text{l}^{-1} \text{sec}^{-1}$  at 436 nm. Spectral sensitivity of apparatus was that indicated in ref. 8

Fig. 2. Mutual sensitization of delayed fluorescence with eosin as donor. Delayed emission spectra of  $5 \times 10^{-4}$  M eosin di-sodium salt in ethanol at  $-75^\circ\text{C}$  with (1) no addition, and (2)  $10^{-4}$  M anthracene. (3) Prompt fluorescence emission spectrum of (1) and (2) at 3,000 times lower sensitivity. Rate of light absorption was  $1 \times 10^{-6}$  einstein  $\text{l}^{-1} \text{sec}^{-1}$ . Spectral sensitivity of apparatus was that indicated in ref. 8

gives any detectable delayed fluorescence with acridine orange hydrochloride as donor. By increasing the pyrene concentration to  $10^{-3}$  M or the benzanthracene concentration to  $10^{-4}$  M, a quite large intensity of delayed fluorescence is observed (column 6 of Table 2). Similarly,  $10^{-6}$  M anthracene, with eosin as donor, shows very weak sensitization at  $22^\circ\text{C}$  (column 5 of Table 1) and no detectable sensitization at  $-75^\circ\text{C}$  (column 7 of Table 2). By increasing the concentration of anthracene to  $10^{-4}$  M, sensitization is observed even at low temperature (column 8 of Table 2 and Fig. 2). Incidentally, the system eosin-anthracene is notable for the considerable anti-Stokes displacement. Thus, when excited with light of wave-length 546 nm, the solution emitted some delayed fluorescence at wave-lengths shorter than 380 nm.

The accuracy of the data shown in Tables 1 and 2 requires some comment. The intensity of sensitized delayed fluorescence varied somewhat with the batch of ethanol used, and some solutions underwent photoreaction during irradiation. The values of  $\theta_A/\phi_A$  are therefore only approximate. The triplet energies of the donors were determined from the positions of the maxima of their  $T \rightarrow S$  emission spectra at  $-75^\circ\text{C}$ . The spectra consisted of single broad bands and it was not possible to locate precisely the O—O transitions. The triplet energies might therefore be situated at wave-numbers up to  $0.05 \mu\text{m}^{-1}$  greater than those recorded. In spite of these difficulties, the results provide a qualitative indication of the relationship between triplet energy-levels and triplet energy transfer efficiencies (process 1) in systems other than those previously investigated. Derivation of values for the efficiency of process (1) from measurements of sensitized delayed fluorescence cannot be attempted until certain anomalous effects (see later) have been satisfactorily explained.

The fact that the delayed fluorescence of acceptor compounds can be selectively sensitized by the choice of a suitable donor suggests a method for the direct analysis of mixtures of fluorescent compounds. Some simple applications of this principle have been discussed elsewhere<sup>12</sup>.

### Mutual Sensitization

Two alternative mechanisms have previously been proposed for the production of sensitized *P*-type delayed fluorescence<sup>7</sup>. Both mechanisms require process (1) as an initial stage, namely:

The first mechanism then proceeds by energy transfer between two acceptor triplets (with or without the formation of an excited dimer as an intermediate):

The second mechanism proceeds in an analogous manner by mixed triplet interaction:

The mixed triplet interaction could, in general, give rise to some single-excited donor molecules:

The addition of low concentrations of acceptor would then produce sensitized delayed fluorescence of the donor.

The results obtained with proflavine hydrochloride as donor and three aromatic hydrocarbons as acceptors are shown in Fig. 1. In the absence of acceptor the delayed emission spectrum (uncorrected for spectral sensitivity of the apparatus) shows weak bands due to the  $T \rightarrow S$  phosphorescence (582 nm) and the *P*-type delayed fluorescence (490 nm) of the donor. With acceptor

Perylene	1.26	0.03	—	0.03	—	0.01	—

Rates of light absorption by the donors were approximately  $6 \times 10^{-6}$ ,  $6 \times 10^{-6}$  and  $1 \times 10^{-5}$  einstein  $\text{l}^{-1} \text{sec}^{-1}$  at 436, 436 and 546 nm for proflavine, acridine O and eosin. \* Refers to acceptor concentrations of  $10^{-3}$  M.

concentrations of  $10^{-6}$  M, the  $T \rightarrow S$  phosphorescence is almost completely quenched, but the delayed fluorescence of the donor increases, and of course, in addition, the sensitized anti-Stokes delayed fluorescence of the acceptors appears at shorter wave-lengths. With benzantracene and pyrene (curves 3 and 4 in Fig. 1), and with benzpyrene (not shown), the sensitization of the donor delayed fluorescence at 490 nm is considerable. Similar results were obtained with acridine orange as donor. With eosin as donor and anthracene as acceptor (Fig. 2) sensitization of the delayed fluorescence of the donor was again observed, although process (1) was relatively inefficient since an anthracene concentration of  $10^{-4}$  M was required to reduce the  $T \rightarrow S$  emission of the eosin (690 nm uncorrected) to 20 per cent of its original value.

### Anomalous Effects

Although these results suggest that mixed triplet quenching can indeed populate the excited singlet state of the donor (by process 5) as well as that of the acceptor (by process 4), there are two features of the results which have not yet been explained. The first concerns the sensitized delayed fluorescence of the donor. At high acceptor concentrations the donor triplet is strongly quenched and process (5) should be almost completely suppressed. Nevertheless, with, for example, benzanthra-

cene at a concentration of  $10^{-4}$  M, the delayed fluorescence of the donor was still observed at an intensity comparable with that shown in Fig. 1. Complex formation between donor and acceptor in the ground state does not seem to be the explanation since the absorption spectrum of the mixture showed no new bands. The second puzzling feature concerns the shape of the sensitized delayed fluorescence spectra of pyrene and benzpyrene. With low acceptor concentrations, both spectra show distortions indicating the presence of another emitting species having a structured spectrum overlapping that of the monomer. Further investigation of both effects is in progress.

## MECHANISM OF CELL DAMAGE DURING FREEZING AND THAWING AND ITS PREVENTION

By DR. J. FARRANT

National Institute for Medical Research, Mill Hill, London, N.W.7

GLYCEROL, dimethyl sulphoxide (DMSO) and several other hydrophilic non-electrolytes, protect cells of many types from damage during freezing and thawing, and allow them to be stored for long periods at low temperatures<sup>1</sup>.

Theories put forward to explain the protective actions of these compounds include prevention of damaging ice crystal formation<sup>2</sup>, and reduction of the concentration of electrolytes at any temperature during freezing<sup>3</sup>. My recent results support the latter. Two new methods have been developed to prevent any rise in electrolyte concentration during cooling to low temperatures. As a result the functional recovery of an organized tissue after re-warming has been greatly improved. The theoretical basis of these methods is as follows.

Fig. 1A shows a solid three-dimensional phase diagram of the three-component system DMSO-NaCl-water. The letter *a* in Fig. 1B denotes a solution containing 0.154 M NaCl in a mixture of DMSO and water (1 : 9 v/v). Its freezing-point is at *b*. It is clear that during further cooling (*bcd*) ice only will separate out until very low temperatures are reached. As ice crystallizes out, the concentrations of both the NaCl and the DMSO in the liquid phase increase. For comparison, *efgh* represents the cooling of the two-component system of NaCl (0.154 M) in water, and *ijkl* indicates the cooling of the two-component system of DMSO (10 per cent v/v) in water.

The curves in Fig. 2 show the effects of varying the initial DMSO concentration on the NaCl concentration at different temperatures during freezing. The initial concentration of NaCl is 0.154 M. The inclusion of as little as 5 per cent v/v DMSO greatly reduces the concentration of NaCl at any temperature as ice separates. Increasing the concentration of DMSO not only lowers the freezing-point progressively, but also markedly reduces the build-up of salt concentration as the temperature is lowered.

With this quantitative information, either of two methods can be used in order to prevent the electrolyte concentration from rising during cooling.

**Method 1.** After incubating the tissue or organ with 5 or 10 per cent v/v DMSO until equilibration is reached at  $+37^{\circ}\text{C}$  (ref. 4), the sample is cooled to the freezing-point and seeded with an ice crystal to prevent supercooling. Afterwards the temperature is lowered very slowly. As ice separates out the volume of the residual liquid phase is kept constant by the addition of a small amount of a solution of DMSO in water at the same temperature. The concentration of DMSO added is the same as that in the liquid phase at that temperature. The addition of the DMSO-water solution can be carried out either in steps or continuously. The most important factor to be considered is that throughout the cooling process sufficient time must elapse to allow the electrolytes throughout the whole system, including the cells, to equilibrate by diffusion. Provided that the liquid volume remains constant the concentrations of all solutes, except DMSO, cannot increase despite the separation of ice. The same concentration-temperature curve can again be followed during the equally slow thawing process. As the ice melts, solutions containing more and more electrolytes but less and less DMSO can be added to keep the electrolyte concentrations constant. This method depends on the diffusion of the electrolytes.

**Method 2.** After the usual incubation in 5 or 10 per cent DMSO at  $+37^{\circ}\text{C}$ , to allow the DMSO to penetrate into the intracellular space, the sample is cooled to within a few degrees of the freezing-point but not allowed to freeze. The concentration of DMSO within the cells is then increased by transferring the tissue to another solution at the same temperature containing the same concentration of electrolytes but an increased concentration of DMSO. After sufficient time has elapsed for

Fig. 1. *A*, Three-dimensional phase diagram of the three-component system DMSO-NaCl-water. The eutectic temperature of the two-component system DMSO-water is  $-136^{\circ}\text{C}$  (*X*), and of the two-component system NaCl-water  $-21^{\circ}\text{C}$  (*Y*). *B*, Magnified view of the ice-liquid interface; *a* is a three-component system of 0.154 M NaCl in a mixture of DMSO and water (1:9 v/v) which freezes at *b* ( $-3.6^{\circ}\text{C}$ ); *e* and *i* represent the two-component systems of NaCl (0.154 M) in water, and DMSO (10 per cent v/v) in water with freezing-points at *f* ( $-0.56^{\circ}\text{C}$ ) and *j* ( $-3.6^{\circ}\text{C}$ ) respectively. When *a* is cooled below its freezing-point ice only separates out (along the curve *bad*), both the DMSO and the NaCl remaining in solution but becoming more concentrated as the temperature is lowered.

diffusion to mix the DMSO completely, outside and inside the cells, the temperature can again be lowered to within a few degrees of the new freezing-point. As in Method 1, the change in DMSO concentration and the reduction in temperature can be carried out either in steps or continuously. Finally, the sample can be stored at  $-79^{\circ}\text{C}$  in the liquid state in a suitable concentration of DMSO (55 per cent v/v). The procedure can be carried out in reverse during slow re-warming. This method depends on the diffusion of DMSO.

Both these methods were theoretically derived using the assumption that NaCl was the only electrolyte present. However, they are still applicable even when the isotonic medium to which the DMSO is added contains a complex mixture of different electrolytes in solution. This is because the basic DMSO-water freezing-point curve is not altered appreciably by the small concentration of electrolytes present in physiological solutions, such as Krebs's solution. The main aim of both these methods is never to allow the solute concentration to exceed the normal levels. The effects of lowering the temperature of a multi-component mixture of electrolytes are complex, but the concentrations of the individual solutes cannot increase above the normal using methods 1 or 2; they can only decrease as each comes out of solution. As yet there is no evidence that cells are permanently damaged by the removal of one or more electrolytes from solution during cooling.

These two new methods of cooling tissues to  $-79^{\circ}\text{C}$  were compared experimentally with the usual cooling method<sup>1,5</sup> using smooth muscle preparations from the guinea-pig. Contractile function in these preparations depends not only on a high percentage survival of cells but also on complete maintenance of the co-ordination between the cells.

Uteri and taenia coli were taken from immature (200–350 g) albino guinea-pigs. The modified Krebs's solution used had the following composition (mM): NaCl, 118; KCl, 4.5;  $\text{CaCl}_2$ , 1.4;  $\text{MgCl}_2$ , 1.16;  $\text{NaH}_2\text{PO}_4$ , 1.16;

$\text{NaHCO}_3$ , 25; dextrose, 11.1. All solutions containing muscles above  $0^{\circ}\text{C}$  were bubbled with  $\text{O}_2$  (95 per cent) +  $\text{CO}_2$  (5 per cent). The functions of the same samples of smooth muscle were tested *in vitro* in an organ bath at  $+37^{\circ}\text{C}$  before and after cooling to  $-79^{\circ}\text{C}$ . Isometric contractile responses were recorded using an M.R.C. strain gauge and a 1-mV potentiometric recorder. Sub-maximal responses were induced by a regularly repeated standard dose of histamine ( $2-3\text{ }\mu\text{g}$  in 20 ml.). After being tested for function, all muscles were incubated for 20 min at  $+37^{\circ}\text{C}$  in 10 per cent v/v DMSO in Krebs's solution. The three methods of cooling and re-warming are described here. Storage time at  $-79^{\circ}\text{C}$  varied between 1 and 24 h.

**Method 1.** The sample was cooled to  $0^{\circ}\text{C}$  in the Krebs's solution containing 10 per cent v/v DMSO. Addition of the different solutions during freezing and re-warming was carried out in steps. The oscillations of the electrolyte concentrations were small and always below the normal value, in order to prevent any risk of a damaging rise in concentration.

**Method 2.** In this method the sample was cooled to  $0^{\circ}\text{C}$  in the Krebs's solution containing DMSO 10 per cent v/v as before. A thread had previously been tied to the muscle, and at each step of the cooling and warming process the muscle was transferred from one solu-

tion to the next. Freezing did not occur.

**Old method.** After being cooled to  $0^{\circ}\text{C}$  in the Krebs's solution with 10 per cent v/v DMSO the sample was cooled at  $2^{\circ}-3^{\circ}\text{C}$  per min to about  $-30^{\circ}\text{C}$  and then at  $4^{\circ}-5^{\circ}\text{C}$  per min to  $-79^{\circ}\text{C}$ . Thawing was accomplished by plunging the tube containing the muscle at  $-79^{\circ}\text{C}$  into a beaker of water ( $+40^{\circ}\text{C}$ ). All ice crystals had vanished within 2 min.

Fig. 2. The effects of varying the initial DMSO concentration on the NaCl concentrations of DMSO-NaCl-water solutions at different temperatures during freezing. In each instance the initial concentration of NaCl is 0.154 M. Increasing the concentration of DMSO reduces the build-up of salt concentration as ice separates during freezing.

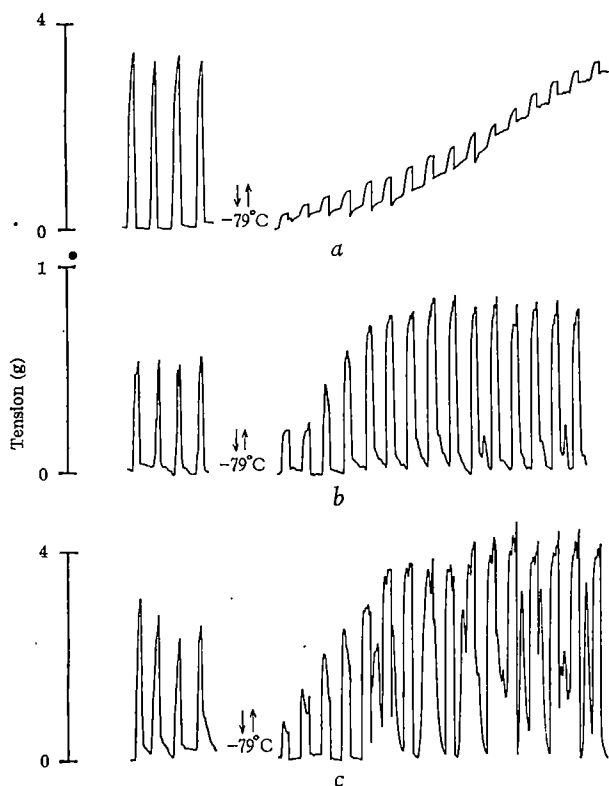

Fig. 3. Isometric contractile responses of uteri to a standard dose of histamine at  $+37^{\circ}\text{C}$  before and after freezing to  $-79^{\circ}\text{C}$ . (a) Cooled by the old method; thawed rapidly. (b) Cooled by method 1; thawed rapidly. (c) Cooled and thawed slowly by method 1. Standard doses of histamine ( $2\text{ }\mu\text{g}$  in a and b;  $3\text{ }\mu\text{g}$  in c) were given at 2-min intervals; contact time 30 sec. Volume of organ bath 20 ml.

Other experiments were performed in which muscles were cooled using methods 1 or 2 but were then thawed rapidly (within 2 min).

After re-warming, all muscles were transferred to a Krebs's solution without DMSO, set up in the organ bath, and tested for contractile function as before.

As previously reported<sup>5,6</sup>, all uteri frozen by the old method contracted spontaneously after thawing and remained contracted (Fig. 3a). Only the addition of EDTA or  $\text{Mg}^{++}$  induced relaxation<sup>6</sup>. In contrast, uteri thawed either slowly or rapidly from  $-79^{\circ}\text{C}$  using method 1 (Fig. 3b and c) or method 2 did not give this spontaneous long-lasting contraction. When either of the new methods was used the mean contractile responses of thawed uteri to the standard dose of histamine were either equal to or greater than the control responses before cooling (Fig. 3b and c). Uteri cooled to  $-79^{\circ}\text{C}$  by all three methods showed spontaneous rhythm after thawing; this effect was much reduced in muscles cooled by method 1 but rapidly thawed (Fig. 3b).

Taenia coli frozen to  $-79^{\circ}\text{C}$  by the old method never contracted after thawing either in response to histamine or spontaneously. By contrast, taenia cooled by methods 1 and 2 contracted in response to histamine after re-warming; unlike the thawed uteri, they showed no spontaneous contraction.

These results leave no doubt that the functional activity of smooth muscle was better preserved by these new techniques of cooling to low temperatures. The basic principle of these two new methods of cooling in the presence of a non-electrolyte is to prevent the concentrations of solutes in the liquid phase from rising above normal values. This was done by adding solutions during cooling and by depending on diffusion to restore equilibrium inside and outside the cells. The fact that cooling either by method 1 (with ice formation) or by method 2 (without ice formation) protects smooth muscle from damage strongly indicates that, for this mammalian tissue

at least, appreciable damage is not caused by ice. This is further evidence that the partial protective effects given by many non-electrolytes, including glycerol, DMSO, and methyl acetamide<sup>7</sup>, are due to their action in reducing the build-up of solute concentrations as the temperature is lowered. Lovelock first suggested this explanation for the protection of erythrocytes by glycerol during freezing. He found that haemolysis of erythrocytes occurred when the concentration of the NaCl in the liquid phase reached mole fraction 0.014 (0.8 M in water) irrespective of the concentration of glycerol<sup>8</sup>. With other cells, partial damage probably occurs before the electrolyte concentration reaches this comparatively high level. Nash has described a range of protective compounds and the physical properties they need in order to interact with water<sup>7</sup>. This interaction enables them to lower the freezing-point of water and reduce the build-up of solute concentrations during freezing in the same way as do glycerol and DMSO. The one criterion is that protective compounds should be non-toxic in the high concentrations which are reached during cooling. If this condition is fulfilled, then these new methods can be used with protective substances other than DMSO provided that an accurate freezing-point curve is determined initially.

Huggins has delayed the formation of ice during the cooling of red blood cells by using a high concentration of DMSO (5.5 M, 39 per cent v/v) in the original medium<sup>9</sup>. These simple non-nucleated cells can tolerate this high concentration of DMSO at  $+37^{\circ}\text{C}$ . Other types of cells cannot. With method 2 the concentration of the protective substance is deliberately increased, but only as cooling progresses. It is important to remember that all biological samples cooled in a 10 per cent v/v DMSO solution by the old method to  $-79^{\circ}\text{C}$  are in contact with a solution of 50.5 per cent v/v DMSO during storage at that temperature. In fact, the damaging or denaturing properties of compounds like DMSO must be greatly reduced by lowering the temperature. Further experiments are necessary to determine the relationship of temperature to the denaturing ability of different concentrations of DMSO and other non-electrolytes.

One other advantage of these new methods is to reduce the problem of the rate of cooling. Hitherto, rates of cooling have been important because, using the usual method of cooling, an increase in the solute concentration still occurs. The amount of damage caused by an excess of electrolyte will depend on three factors: the actual concentration of electrolyte, the temperature, and the time that the excess concentration is left in contact with the living cell. Despite the fact that, with the old method, reducing the temperature will increase the concentration of electrolytes during freezing, the lower the temperature the lower will be the chemical potential of the electrolytes. The combination of these factors will therefore determine the optimal rates of cooling. By contrast, using method 1 or 2, smooth muscle cells, at least, can be kept for several hours at temperatures as high as  $-5^{\circ}\text{C}$  or  $-15^{\circ}\text{C}$  without electrolyte damage. Since changes of concentration need only occur very slowly, damage due to sharp osmotic imbalances on either side of cell membranes can also be avoided.

If very long-term storage is required, samples should be kept at the temperature of liquid nitrogen ( $-196^{\circ}\text{C}$ ) rather than that of solid carbon dioxide ( $-79^{\circ}\text{C}$ ). The increase in electrolyte concentration which must occur just before the whole system solidifies between  $-79^{\circ}\text{C}$  and  $-196^{\circ}\text{C}$  will not damage the cells at these very low temperatures, provided that normal concentrations have not been exceeded between  $0^{\circ}\text{C}$  and  $-79^{\circ}\text{C}$ .

Until now, recovery of viable cells and tissues from low temperatures has necessitated rapid thawing. The small muscle samples used in the present experiments were easy to thaw rapidly and tolerated the process well. Rapid thawing has itself caused problems with larger samples of other cells and tissues as well as with organs

because of the difficulty of rapid heat transfer. The slow thawing procedures used in both method 1 and method 2 will avoid these difficulties.

The most important advantage of method 2 over method 1 is that, because freezing is avoided, it may be possible to devise a similar method for cooling organs, by perfusing higher and higher concentrations of protective substances at lower and lower temperatures. Experiments to attempt this are planned with the heart.

In the past many cells have been partially protected from damage during freezing and thawing by the use of added non-electrolytes. This is a tribute to the capacity of these cells to withstand exposure to raised electrolyte concentrations, even if these concentrations are much lower than would be reached without the non-electrolytes. The complete prevention of any increase in the concentration of salts may lead to the successful recovery of more sensitive cells and to an improved recovery of the others.

Two final words of caution should be given. First, the most important practical difficulty of these two new methods is in deciding when the process of diffusion has equilibrated the concentrations of ions (method 1) or of DMSO (method 2) at each temperature. Until quantita-

tive values for the diffusion of ions and DMSO have been computed for different conditions of temperature and tissue type and size, estimation of this time factor must be approximate. Secondly, the longer time taken for cooling and re-warming increases the relative importance of possible harmful effects of high concentrations of DMSO or of any other protective agent at low temperatures.

Once these problems are overcome it may be that these new methods will form the basis for the successful freezing, storage and thawing of tissues which require 100 per cent cell survival in order to function.

I thank Drs. J. E. Lovelock, T. Nash and Audrey U. Smith for their advice, and Miss L. Staniford and the staff of the Engineering Division of the National Institute for Medical Research for their technical assistance.

## DISTRIBUTION OF TRITIATED THYMIDINE IN VARIOUS TISSUES

By DR. S. R. PELC and T. C. APPLETON

Medical Research Council, Biophysics Research Unit, King's College, 26-29 Drury Lane, London, W.C.2

AFTER injection into animals tritiated thymidine is distributed by the bloodstream and finds its way into cells. It is then incorporated into DNA by those cells that are in a suitable metabolic state, and thymidine not utilized is broken down. Measurements have shown that the average number of grains per nucleus reaches its maximum 40-60 min after injection<sup>1,2</sup>. It seemed of interest to determine directly the availability of tritiated thymidine to the various types of cells in a number of organs.

In one experiment adult mice weighing 22-25 g were given intraperitoneal injections of 50  $\mu$ Ci tritiated thymidine and killed 15 min, 30 min and 1 h after injection. After dissection, organs were immediately frozen by immersion in isopentane cooled in liquid nitrogen. Autoradiographs were prepared by a technique which allows the retention of the soluble labelled compounds as described by Appleton<sup>3</sup>. Frozen sections were cut at 5-6  $\mu$  on a 'Pearse' cryostat kept in a darkroom and operated under a red safelight. Coverslips were covered with Kodak 'AR10' stripping film so that the photographic emulsion faced outwards, then dried and cooled to -5° C. Frozen sections were transferred by touching the cold coverslips against the sections and the preparations exposed at a temperature of -20° to -30° C. After exposure the sections were fixed in 5 per cent acetic alcohol for 1 min, washed in tap water, and then processed in Kodak 'D19b' developer and acid fixer. After being washed and dried the preparations were stained with haematoxylin and eosin. Autoradiographs of well-labelled nuclei were invariably above the nuclei, indicating that the film and tissue were firmly bonded together, and that no slipping occurred during processing or exposure. Autoradiographs of fixed and embedded material were also prepared.

Most cells in all tissues investigated show nuclear and cytoplasmic labelling 15 min after injection, while after 30 min the autoradiographs are considerably weaker. 1 h after injection the grain numbers are lower still, though definitely above background, and after 24 h the counts are nearly equal to background except over cells which have incorporated tritiated thymidine into DNA.

Such cells are found in varying proportions at all times in epithelial cells and smooth muscle surrounding the colon and seminal vesicle, and in brain, as well as in the dividing organs (intestine, oesophagus).

The number of photographic grains per unit area was counted in various tissues by using a square eye-piece aperture. Heavily labelled nuclei were disregarded. Fig. 1 shows that after intraperitoneal injection the concentration of grains is highest in smooth muscle, somewhat lower in epithelial tissues, and lowest in brain, probably owing to the blood-brain barrier.

In another experiment adult mice were given an intraperitoneal or intravenous injection of 50  $\mu$ Ci tritiated thymidine and killed 2 min after injection; water-soluble autoradiographs were prepared as described. In the smooth muscle from the colon of a mouse which had been given an intravenous injection (Fig. 2) the label is evenly distributed throughout the muscle. On the other hand, in smooth muscle (colon) from a mouse which had been given an intraperitoneal injection (Fig. 3) thymidine can be seen diffusing in from the peritoneal fluid surrounding the intestine, irrespective of the direction of the muscle fibres or nuclear membranes. The speed of diffusion is approximately 2  $\mu$ /sec.

Fig. 1. Distribution of tritiated thymidine in various tissues of the mouse. The unit area for grain counting (72  $\mu^2$ ) was determined by an eye-piece aperture. Nuclei showing high labelling were assumed to have incorporated tritiated thymidine and were omitted. Crosses, smooth muscle (colon); triangles, colon; stars, brain; open circles, smooth muscle (seminal vesicle); closed circles, seminal vesicle.

Fig. 2. Water-soluble autoradiograph of the distribution of tritiated thymidine in smooth muscle of the colon 2 min after intravenous injection. Note the even labelling throughout the muscle. (Haematoxylin and eosin,  $\times 400$ )

Fig. 3. Water-soluble autoradiograph of the distribution of tritiated thymidine in smooth muscle 2 min after intraperitoneal injection. The thymidine can be seen diffusing in from the peritoneal fluid bathing the outside of the gut; the diffusion appears to be unaffected by nuclei or muscle fibres. (Haematoxylin and eosin,  $\times 400$ )

Grain counts (Table 1) show that after intravenous injection the concentration in mouse intestine is approximately equal in the epithelium and in the smooth muscle.

Using an eye-piece aperture of apparent diameter equal to that of cell nuclei, the grain density over nuclei and cytoplasmic areas in brain was counted (Figs. 4, 5 and 6).

15 min after injection, the cytoplasm shows a reasonably random distribution of grain densities while some of the nuclei contain considerably more than others. After 30 min a few nuclei show more grains than the equivalent areas of cytoplasm, while after 1 h the distribution over nuclei and cytoplasm is almost equal. Similar differences between labelling of nuclei and cytoplasm were observed in other tissues, though no detailed counts were undertaken. In brain the average count per unit area over nuclei is 3.8 grains and 1.1 grains over cytoplasmic areas. Measurements have shown that approximately 10 per cent of the area of a section is nuclear, hence 27.8 per cent of the labelled material is in the nuclei and 72.2 per cent in the cytoplasm. After 30 min the concentrations are 0.9 grains per unit area over nuclei and 0.7 over cytoplasm, and at 60 min 1.2 grains for nuclei and 1.6 for

Table 1. TRITIATED THYMIDINE IN MOUSE INTESTINE AFTER INTRAVENOUS INJECTION

Time (min)	Grains/unit area	
	Epithelium	Smooth muscle
2	12.9	15.6
5	12.7	12.9
10	10.7	10.3
20	2.5	2.9

Time: time from injection to death of animals. Grains per unit area: see note to Fig. 1. Corrected for background.

cytoplasm. These figures have been corrected for background. After 30 min and 60 min the concentrations are approximately equal and therefore 10 per cent is in the nuclei and the remainder in the cytoplasm. Nevertheless a number of nuclei still show more grains than would be expected from a random distribution (Fig. 6). In previous work<sup>4</sup> tritiated thymidine was found to be incorporated into DNA in only 0.24 per cent of the cells of the central nervous system; the labelled nuclei counted here in considerable numbers are therefore unlikely to be permanently labelled.

Grain counts over well-labelled nuclei in water-soluble autoradiographs and stripping film autoradiographs of fixed and embedded organs showed no significant difference. Feinendegen and Bond<sup>5</sup> found higher concentrations of tritiated thymidine in bone marrow in cell types capable of division than in the non-dividing ones. Unless the discrepancy between their findings and ours is due to differences in technique it has to be assumed that bone marrow cells differ from those in other organs in permeability to thymidine.

Fig. 4. Grain distribution in brain, 15 min after injection of tritiated thymidine. An eye-piece aperture of the apparent size of the nuclei was used to count grains over 300 nuclei and 300 cytoplasmic areas. Above, cytoplasm; below, nuclei

Fig. 5. Grain distribution in brain, 30 min after injection. See remarks to Fig. 4. Above, cytoplasm; below, nuclei

Fig. 6. Grain distribution in brain 1 h after injection. See remarks to Fig. 4. Above, cytoplasm; below, nuclei

It can be concluded that: (a) tritiated thymidine is available to the cytoplasm and nuclei of nearly all cells in the organs investigated; (b) since only a proportion of nuclei are found to be permanently labelled, availability of thymidine in itself is not sufficient to initiate incorporation of thymidine into DNA, nor does it to any extent stimulate it; (c) the amount of tritiated thymidine which diffuses into all cells in an organ is sufficient to explain the degree of uptake in well-labelled nuclei if it is assumed that such cells retain all the thymidine entering the cell and that the contents of soluble material are 'turned over' once every 3-5 min; (d) the incorporation of tritiated thymidine in the more heavily labelled nuclei of the central nervous system in excess of that expected from random labelling may be due to a different permeability of some nuclear membranes or the formation of an intermediate compound; (e) in view of the short time of availability of tritiated thymidine, the site of injection can seriously affect the total amount of tritiated thymidine reaching the cells, and therefore comparison of grain numbers over labelled nuclei in different organs may be subject to substantial errors.

## SECRETION OF THYROCALCITONIN

By DR. A. D. CARE

The Rowett Research Institute, Bucksburn, Aberdeen

DURING recent months a good deal of controversy has centred round the hypocalcaemic factors secreted by the parathyroid and thyroid. Copp *et al.*<sup>1</sup> have demonstrated that hypercalcaemic perfusion of a dog's thyroid along with its parathyroid glands resulted in a more rapid fall in the systemic plasma calcium concentration than could be accounted for in terms of mere inhibition of parathormone secretion. Moreover, they showed that cross-transfusion of thyro-parathyroid venous plasma from such a stimulated gland preparation into an intact dog caused a sharp decrease in the plasma calcium concentration. No significant change in calcium concentration was associated with hypercalcaemic perfusion of the thyroid from which all parathyroid tissue had been removed. Using sheep, in which species two superior parathyroids are found near the apices of the thymus and only one in each lobe of the thyroid, Copp and Henze<sup>2</sup> demonstrated a hypocalcaemic response to hypercalcaemic perfusion of the superior parathyroid but no response when one lobe of the thyroid with its small parathyroid were similarly perfused. From these and other results, Copp *et al.*<sup>1</sup> conclude that a hormone having a hypocalcaemic action is secreted by the parathyroid in response to hypercalcaemia. This parathyroid hormone they called 'calcitonin'. On the other hand, using goats, in which the anatomical arrangement of parathyroids and thyroids is similar to that found in sheep, Foster *et al.*<sup>3</sup> failed to demonstrate the secretion of calcitonin in response to hypercalcaemic perfusion of the superior parathyroid.

In contrast to the foregoing work carried out on anaesthetized animals, a conscious sheep preparation<sup>4</sup> was devised, and with it Care and Keynes<sup>5</sup> clearly demonstrated that the parathyroids are a source of a hypocalcaemic hormone, similar in its time course of action to calcitonin.

Hirsch *et al.*<sup>6</sup> postulated the release of a hypocalcaemic factor from parathyroid-free thyroid which they termed thyrocalcitonin, and Hirsch and Munson<sup>7</sup> and Baghdiantz *et al.*<sup>8</sup> have all prepared purified extracts of thyroid tissue

which exhibit potent hypocalcaemic effects in both intact and parathyroidectomized animals. Both groups of workers suggest that calcitonin and thyrocalcitonin are the same substance and that this is secreted by the thyroid. However, no unequivocal evidence for the release of thyrocalcitonin in response to hypercalcaemic perfusion of a thyroid free from parathyroid and undamaged by surgical interference has so far been provided. Such evidence is presented here.

**Operative procedures.** Pig thyroid has been reported to contain no parathyroid tissue<sup>9</sup> and this was confirmed by the examination of serial sections by light microscopy. Two castrated Large White male pigs were used of live weight 35-40 kg. Anaesthesia was induced by the intravenous administration of a mixture of 30 per cent methohexital sodium (25 mg/ml.) and thiopentone (50 mg/ml.); it was maintained under halothane and oxygen. Food was withheld for the 24 h preceding the experiment.

The neck was incised longitudinally and the thyroid exposed. Since, in the pig, the manubrium of the sternum often extends over the thyroid vein, 1-2 cm of this was removed and the attached muscles were ligated and cut. The stump of the manubrium was plugged with bone wax. Careful dissection revealed the thyroid vessels. The right thyroid artery is a branch of the inferior cervical artery in the typical case, although it has been observed as a branch of the common carotid artery. The left and right thyroid veins soon fuse to form a single vessel which joins the junction of the left and right innominate veins (Fig. 1).

The right inferior cervical artery was catheterized with siliconed polyvinyl chloride tubing (ext. diam. 2.0 mm) cranial to the point of emergence of the thyroid artery. The left common carotid artery was catheterized with siliconed polyvinyl chloride tubing (ext. diam. 3.0 mm). A loose ligature was placed round the thyroid vein close to its junction with the innominate veins. The left external jugular vein was catheterized with polythene tubing (ext. diam. 1.2 mm).

Fig. 1. The location and principal blood supply of the thyroid gland in the pig, showing the method of hypercalcaemic perfusion of the gland. A portion of the manubrium has been removed to show the whole of the thyroid vein. The parathyroid glands are in the thymus and have been left intact.

After surgery had been completed, each pig was heparinized initially with 7,500 i.u. heparin and a further 5,000 i.u. administered every 1-1.5 h. The outflow catheter was connected via siliconed polyvinyl chloride tubing to the inflow catheter in such a way that the rate of flow could be controlled by means of a roller pump so that the perfusion pressure was maintained at least 20 mm in excess of the systolic blood pressure. This flow rate was usually 5-8 ml./min. By means of a constant infusion pump Krebs-Henseleit Ringer solution, supplemented with calcium chloride, was added to the blood at the rate of either 0.1 or 0.2 ml./min. Inflow blood samples could be obtained from a tap on the inflow catheter and systemic blood samples from a tap on the outflow catheter. When the circuit was established and the rate of calcium supplementation of the perfusing blood adjusted to give a suitable resultant plasma calcium concentration (7 m.equiv./l.), a small bulldog clip was placed on the right inferior cervical artery caudal to its junction with the thyroid artery.

In order to maintain a constant content of ionized calcium within the pig, a suitable concentration of the di-sodium salt of ethylenediamine tetraacetic acid (EDTA) dissolved in 0.9 per cent saline was infused at 0.5 ml./min via the catheter in the left external jugular vein. The EDTA concentration was adjusted to compensate for the additional calcium used to perfuse the thyroid.

Approximately 2 h after termination of surgery, hypercalcaemic perfusion of the thyroid commenced along with systemic infusion of compensatory EDTA. 2 h later the EDTA infusion was stopped, the thyroid vein quickly catheterized, using siliconed polyvinyl chloride tubing (ext. diam. 2.0 mm) of approximate length 25 cm, and thyroid venous blood collected for about an hour in an ice-cooled vessel held about 20 cm below the level of the thyroid. Systemic plasma samples were obtained at regular intervals and analysed for calcium, magnesium, inorganic phosphate and total solids.

The thyroid venous blood was quickly centrifuged and the plasma stored at 1° C. After 20 h at 1° C, 48 ml. of the plasma was injected intravenously into a similar pig and the effect on systemic plasma calcium concentration noted. In another experiment, 22 ml. thyroid venous plasma was injected intravenously into a 1½-year-old

Greyface female sheep (live weight 46 kg) and the calcium concentration in serial venous plasma samples measured.

**Analysis.** Plasma was usually separated within 15 min of sampling and calcium concentration was determined immediately afterwards by titration against EDTA with murexide indicator, using a photoelectric cell to locate the end-point. Plasma total solids were also quickly estimated by use of a T.S. meter (American Optical Co., Buffalo, N.Y.). Plasma magnesium concentration was measured by atomic absorption spectroscopy<sup>10</sup>. In the expression of the results, plasma calcium and magnesium concentrations have been corrected for changes in plasma total solids. The coefficient of variation associated with the plasma calcium concentration is  $\pm 0.7$  per cent and that with the plasma magnesium concentration  $\pm 1.3$  per cent. The estimation of the plasma inorganic phosphate according to the method of Hall<sup>11</sup> was also started immediately after the plasma had been separated. The coefficient of variation of this method is  $\pm 1.5$  per cent.

**Results.** Fig. 2 shows the pronounced fall (30 per cent) in plasma calcium concentration associated with hypercalcaemic perfusion of the thyroid for 2-2.5 h. There was no concomitant fall in plasma magnesium or inorganic phosphate concentrations. Drainage of thyroid venous blood resulted in a slow rise in not only the plasma calcium but also the plasma magnesium concentrations.

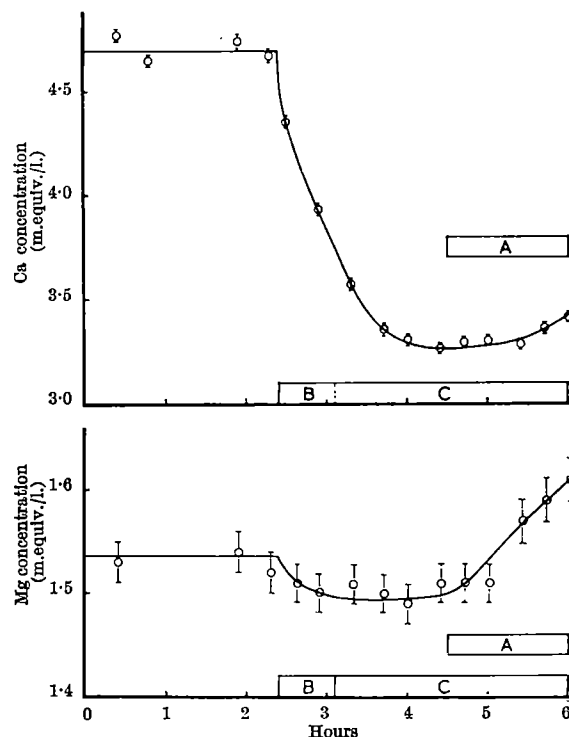

Fig. 2. The changes in systemic plasma calcium and magnesium concentration associated with hypercalcaemic perfusion of the pig thyroid *in situ* under halothane, oxygen anaesthesia. B, Perfusion calcium concentration 10 m.equiv./l. C, Perfusion calcium concentration 7 m.equiv./l. A, Drainage of thyroid venous blood. For each plasma sample the standard deviation associated with the analytical technique used is shown by a vertical line.

The intravenous injection of the perfused thyroid venous plasma into another pig resulted in a small but significant decrease in the plasma calcium concentration (Fig. 3). In another experiment a 12 per cent fall in plasma calcium concentration was observed in the donor pig, but no effect was obtained following the intravenous injection of the perfused thyroid venous plasma into a sheep. No significant change in magnesium concentration of the plasma of either sheep or pig was noted after cross-transfusion of perfused thyroid venous plasma.

Fig. 3. The effect on the plasma calcium concentration of a conscious pig transfused intravenously with 48 ml. thyroid venous plasma (D) obtained by drainage of thyroid venous blood during hypercalcaemic perfusion of the thyroid

**Discussion.** The very degree of hypocalcaemia associated with hypercalcaemic perfusion of the thyroid is suggestive of the secretion of a specific calcium-lowering hormone rather than of some inhibition of parathormone secretion associated with the experimental technique. This conclusion is confirmed by the hypocalcaemic response to the cross-transfusion to another pig of venous plasma from such a stimulated thyroid. In view of the relatively large response noted in the donor pig, one might have expected an effect in the recipient pig larger than was in fact observed. Thyrocalcitonin may be unstable when stored in plasma at 1° C, which may account for the lack of effect after cross-transfusion to a sheep, since pig thyroid extracts, rich in thyrocalcitonin, have been shown to exert a hypocalcaemic action in the sheep (D. H. Copp, personal communication).

The slow rise in plasma calcium concentration which accompanied the drainage of thyroid venous blood was presumably the result of parathormone action, since the parathyroid glands were left intact. The similar rise in plasma magnesium concentration may have had a similar cause but may also have been affected by the drainage of thyroxine. In other experiments, the administration of either thyroxine or tri-iodothyroxine to sheep has been shown to result in a hypomagnesaemic response unaccompanied by hypocalcaemia.

The rapid hypocalcaemic response to hypercalcaemic perfusion of the thyroid is not unlike that observed during similar perfusion of the parathyroid<sup>2,5</sup>, although a good deal greater in magnitude. However, the mass of tissue perfused is also greater in the case of the thyroid. A difference, however, lies in the lack of effect of thyrocalcitonin on plasma magnesium concentration relative to that shown by parathyroid calcitonin.

There would now seem to be little doubt that both the parathyroid and the thyroid secrete calcium-lowering hormones in response to hypercalcaemic perfusion; however, the relative importance of each in calcium homeostasis remains to be determined.

## AGAR GEL-ELECTROPHORETIC ESTERASE PATTERNS IN HOUSEFLIES

By [the late] DR. K. VAN ASPEREN and Miss M. E. VAN MAZIJK

Laboratory for Research on Insecticides, Wageningen, Holland

**I**NVESTIGATIONS on esterases and organophosphate resistance in the housefly (*Musca domestica*) revealed the occurrence of a large number of different esterases<sup>1</sup>. Detailed agar gel-electrophoretic investigations of one particular strain of flies (strain C) demonstrated the occurrence of ten different esterases capable of hydrolysing  $\alpha$ -naphthyl acetate. Single individuals were found to contain 3–8 out of these 10 esterases. Genetical investigations showed the occurrence of these esterases to be controlled by 9 different genes on 8 different chromosomal loci<sup>1,2</sup>.

In this article emphasis will be laid on the great diversity of agar gel-electrophoretic patterns obtained with different strains of houseflies. Homogenates in distilled water of either at least 30 flies or individual flies, at a concentration of 10 flies/ml., were centrifuged at 20,000g for 30 min and the supernatants used for agar gel-electrophoresis on microscope slides according to Wieme<sup>3</sup>. Esterases were demonstrated as brownish bands in the gel by the addition of  $\alpha$ -naphthyl acetate and diazo-blue<sup>2</sup>.

Fig. 1 shows the patterns obtained for mass-homogenates of 11 strains of flies. Electrophoretic experiments on single individuals showed that the patterns obtained with mass-homogenates are built up from dissimilar

individual contributions. In Fig. 2 examples are given for the strains F<sub>c</sub> and H. Adding these results to those previously obtained for strain C, it seems reasonable to state that strains of houseflies, originating from different parts of the world and some of them also having particular histories of laboratory breeding and selection, show highly strain-specific electrophoretic esterase patterns; moreover, that these patterns are the resultant of both intensity and frequency of the esterase bands contributed by the individual flies in each population. Investigations carried out at intervals of 8 months to 2 years showed the strain patterns to be constant over periods of time representing 15–50 generations. Only one of the esterases was present in all individuals of all strains, that is, that nearest the cathode. This is not the cholinesterase, since this has previously been proved to move slowly to the anode<sup>5</sup>. Under the conditions used in the experiments recorded here, the cholinesterase does not show up as a distinct band, probably because it is largely particulate.

In a previous investigation<sup>6</sup> it was shown that nearly all the fly-strains in our laboratory which are resistant to organophosphorus insecticides have considerably lower esterase activities to  $\alpha$ -naphthyl acetate than the susceptible strains. In a series of papers<sup>1,4,6–8</sup> evidence has been produced that this is due to the absence from

Table 1

Protein contents and esterase activities in the supernatants obtained after centrifugation of whole homogenates without deoxycholate (-D) and with deoxycholate (+D). Protein contents were determined according to the Folin-Ciocalteu method (ref. 9) after 10 times dilution of the supernatant, which gives a concentration of 1 fly/ml., and are expressed in mg/ml. Esterase activities in the presence of  $10^{-7}$  M eserine were determined according to a method that has been previously described (ref. 6). One ml. of 500 times diluted supernatant ( $\sim 0.02$  fly/ml.) was incubated with 5 ml. of eserinated  $\alpha$ -naphthyl acetate solution (0.003 M) for 30 min. After that 1 ml. of a diazo blue-lauryl sulphate reagent was added and optical density measured at 600 m $\mu$  and 1 cm light path. The values thus obtained are given as 'esterase activity'. Strains: *ct* and *bac* (= *bub*; *acv*; *car*), carrying recessive marker genes, were obtained from Dr. T. Hiroyoshi, Osaka University, Japan. See also legend to Fig. 1.

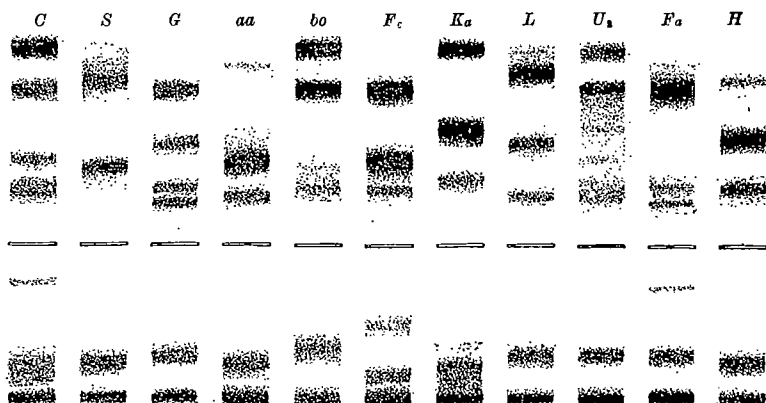

Fig. 1. Electrophoretic esterase patterns in 11 strains of houseflies. Top, anode; bottom, cathode. Data on the origin, further history and properties of the strains C, S, G, F<sub>c</sub>, K<sub>a</sub>, L, U<sub>a</sub>, F<sub>a</sub> and H are given elsewhere<sup>1,2</sup>. aa=strain *ar:ac* and bo=strain *bub:ocra*, each carrying two recessive marker genes, were obtained from Dr. R. Milani, Pavia, Italy

the organophosphate-resistant strains of a single ali-esterase, which in the susceptible strains is responsible for approximately 85 per cent of the total non-eserine-sensitive esterase activity. This ali-esterase has been named the ali-esterase *a*.

Ali-esterase *a* was found to be mainly particulate. High-speed centrifugation removes most of it, and consequently, if supernatant activities were compared, the difference between susceptible and resistant strains was much less than that observed if total homogenates were compared. It is, however, possible to solubilize the ali-esterase *a* by the addition of 0.005 M deoxycholate. This is clearly borne out by the results in Table 1, which gives the protein contents and ali-esterase activities of

the supernatants, obtained with and without deoxycholates of 5 organophosphate-susceptible and 5 organophosphate-resistant strains. Protein contents of all strains and ali-esterase activities in the resistant strains were only about 50 per cent higher with deoxycholate, whereas the ali-esterase activities in the supernatants of the organophosphate-susceptible strains were approximately six times higher after deoxycholate treatment. Electrophoretic esterase patterns of supernatants of deoxycholate-treated homogenates showed a very active anodically moving esterase to be present in the organophosphate-susceptible and not in the organophosphate-resistant strains. Its position is roughly similar to that of the fastest-moving esterase of strain S. Semi-quantitative determinations of the esterase activities in the agar gel by incubation

of gel-strips with  $\alpha$ -naphthyl acetate in test-tubes indicated that this esterase represents about 80 per cent of the total activity in the gel.

Unfortunately, nothing is known about the natural function and the natural substrate of the esterases examined, and the diversity of esterase patterns raises some questions. The many esterases may have some common function, which can be performed by different sets of iso-enzymes, that is, the difference in electrophoretic mobility could be caused by functionally non-essential differences in structure. However, flies which survived a rather low dose of the insecticide diazinon were found to be devoid of all esterase bands except the most cathodical one, but still were quite normal in behaviour. This could indicate that, with the possible exception of the most cathodically moving one, the esterases examined do not have a very essential function in normal adult life. Their evolutionary importance under natural conditions can only be guessed at, but little doubt now exists that the occurrence of some of the esterases is intimately connected with their ability to survive treatment with organophosphorus insecticides. The significance in this respect of the ali-esterase *a* and genetically related enzymes has been well established<sup>1,4,7</sup> and the results of further investigations will be published soon.

## QUANTITATIVE EXAMINATION AND ANALYSIS OF THE PROZONE PHENOMENON IN THE HAEMAGGLUTINATION REACTION

By DR. HAROLD S. GOODMAN and LILLIAN MASAITIS

Michael Reese Research Foundation, Chicago, Illinois

THE inhibition of agglutination associated with excess antibody has been attributed either to a saturation of the antigenic sites by excess antibody<sup>1</sup> or to a competitive inhibition by blocking antibodies<sup>2</sup>. Although these hypotheses are often presented as opposing views of the prozone phenomenon, Renton and Hancock<sup>3</sup> effectively showed their essential similarity. However, they also demonstrated the inadequacies of these hypotheses to explain fully the prozone phenomenon.

A recent investigation carried out in this laboratory was concerned with the analysis of the haemagglutination reaction<sup>4</sup> and emphasized the importance of factors which affect either the number or strength of antigen-antibody linkages formed between cells. Heterogeneity of both antigen and antibody combining sites with respect to their contribution to the stability of the antibody linkages formed between cells was assessed in this investigation. It was felt that a direct consideration of the influence of these factors on the agglutination occurring in excess antibody would provide a more comprehensive picture of the prozone phenomenon. Moreover, using a quantitative agglutination procedure the prozone phenomenon could be examined with greater accuracy and in greater detail than had been previously possible with conventional agglutination techniques.

The quantitative procedure used in this investigation depends on the fact that agglutination results in a reduction in free cell concentration. The Coulter electronic cell counter (Coulter Electronics, Hialeah, Florida) has provided a practical means of measuring free cell concentration and therefore a means of quantitating red cell agglutination<sup>5</sup>. In this procedure antiserum in graded dilutions is added to a series of silicone-treated 15-ml. cylindrical glass vials. Sufficient buffered saline is added to give a volume of 5 ml. Then 5.0 ml. of a washed red cell suspension containing  $4.0 \times 10^6$  cells per ml. is added to each vial. Cell standards consisting of only cells and buffered saline are routinely included. In this particular application of the quantitative agglutination procedure, all vials are allowed to stand undisturbed at 25° C for 1 h to permit sensitization. Because of the low cell concentration, little or no agglutination occurs during this period, but primary union of antigen and antibody does occur<sup>6</sup>. The vials are further incubated at 25° C for 2 h with mechanical mixing on a stirring device specially designed to provide uniform mixing. The free cell concentration is determined for the contents of each vial with the Coulter counter from which the percentage agglutination is calculated.

An example of the quantitative measurement of agglutination occurring over a wide range of antiserum concentrations is shown in Fig. 1. Agglutination is expressed as a percentage and plotted on an arithmetical scale. Antiserum concentration is plotted on an arithmetical scale in the inserted figure and on a log scale in the main figure. Expressing antiserum concentration as a logarithm has the advantage that proportional changes in antiserum concentration are graphically equivalent, allowing agglutination curves obtained with antisera of widely different titres to be directly compared. The quantitative agglutination curve shown in Fig. 1 exhibits

three general zones associated with the progressive increase in antiserum concentration. There is an initial zone of increasing agglutination, followed by a zone of maximum agglutination and a final zone (prozone) characterized by a progressive reduction in the percentage of agglutination.

Fig. 2 compares the quantitative agglutination curves of four anti-A and four anti-Rh<sub>0</sub> sera. Cells from a single donor were used to test the antisera of each group so that the curves within each group may be directly compared. Antiserum 15 shows the strongest agglutinating properties of the four anti-A sera. This serum gave the highest percentage agglutination and showed no detectable inhibition at the highest antiserum concentration tested. Antisera 19 and 28 gave somewhat lower agglutination maxima with inhibition of agglutination at moderate concentrations of antiserum. Antiserum 1891 appears to be the weakest, giving an agglutination maximum of only 47 per cent and inhibition at relatively low antiserum concentrations. Differences in the slopes of these curves in antibody excess indicate that these antisera contain different distributions of antibody molecules with respect to their agglutinating properties. The smaller secondary peak observed with antiserum 1891 suggests the presence of a minor secondary antibody population. The agglutination curves obtained with the anti-Rh sera show less variability than the curves obtained with the anti-A sera. In addition, the agglutination obtained with the anti-Rh<sub>0</sub> sera and papain-treated red cells<sup>7</sup> was inhibited by a relative low excess of antiserum as indicated by the comparative narrowness of the Rh curves.

In contrast to the previous experiment, agglutination curves obtained with different cell populations are compared in Fig. 3. Cells from four A Rh positive individuals were examined with a single anti-A serum and a single anti-Rh<sub>0</sub> serum. In their reaction with the anti-A serum cells 2 and 3 gave curves similar to each other, but different from the curves obtained with cells 1 and 4. These latter cells gave more agglutination at lower antiserum concentrations and their agglutination was also more readily inhibited by excess antibody. When these same cells were tested with the anti-Rh<sub>0</sub> serum a different pattern of curve was

Fig. 1. Plot of percentage agglutination against log-antiserum concentration (anti-A serum and A<sub>1</sub> red cells). In the insert an arithmetic plot of antiserum concentration is shown for comparison.

Fig. 2. Comparison of quantitative agglutination curves obtained with two different groups of antisera (anti-A and anti-Rh<sub>0</sub>). Each group of antisera was tested with cells obtained from a single donor. Differences within each group are, therefore, due to differences in the individual antibody populations

obtained. Cell 1 showed the least inhibition of agglutination by excess antibody and cell 4 gave the lowest maximum percentage agglutination. Cells 2 and 3 were intermediate in their behaviour. These results illustrate the variability of the antigenic characteristics found between cell populations and the effect this variability has on the quantitative agglutination curve.

In the foregoing experiment it was not possible to distinguish between the effect of number and binding strength of the antigenic sites. It was, therefore, of interest to design an experiment in which the number of antigenic sites/cell would be the sole experimental variable. This was accomplished by simply using different concentrations of a purified protein antigen (human 7S  $\gamma$ -globulin) coupled to aliquots of a tanned red cell suspension<sup>8</sup> and testing with an appropriate antiserum (rabbit anti-human  $\gamma$ -globulin). In Fig. 4 the effect of reducing the number of antigenic sites/cell on the quantitative agglutination curve is shown. A progressive weakness of the agglutination curve can be seen with reduction in the concentration of antigen used for coupling. In antigen excess a greater concentration of antiserum was required to obtain the same percentage agglutination at a reduced number of antigenic sites/cell with the maximum percentage agglutination correspondingly reduced. In antibody excess there was a progressive percentage increase in the inhibition of agglutination.

Differences in the agglutinability of A<sub>1</sub> and A<sub>2</sub> cells were previously concluded to be due to both a difference in the number and strength of antigenic sites/cell<sup>9</sup>, that is, A<sub>2</sub> cells have fewer and weaker antigenic sites than A<sub>1</sub> cells. For this reason it was of interest to examine the quantitative agglutination curves obtained with these cells. A comparison of agglutination curves obtained with a number of anti-A sera tested with A<sub>1</sub> and A<sub>2</sub> cells, rather

surprisingly, gave two extremes in behaviour. An example of each is shown in Fig. 5. Antiserum 23 gave an agglutination curve with A<sub>2</sub> cells shifted to the right and somewhat weaker than that obtained with the A<sub>1</sub> cells. Antiserum 1891 with A<sub>2</sub> cells also shows an agglutination curve shifted to the right; however, in contrast to what might be expected, the A<sub>2</sub> curve is higher and broader than the curve obtained with A<sub>1</sub> cells. The comparatively weak agglutination curve of antiserum 1891 with A<sub>1</sub> cells suggests that this antiserum contains a high proportion of weakly agglutinating antibody molecules. The stronger agglutination curve obtained with the A<sub>2</sub> cells further suggests that a considerable portion of these weakly agglutinating antibody molecules was unable to combine with the A<sub>1</sub> cells which provided an opportunity for only the more strongly agglutinating antibody molecules to combine with these cells.

The foregoing experiments provide a number of points pertinent to the prozone phenomenon. In order to clarify these findings, the prozone phenomenon with respect to the basic factors responsible for agglutination will be considered in greater detail.

Haemagglutination has been shown to be the result of the random collision of red cells<sup>6</sup> with the formation of cross-linkages between antigenic sites on the surface of the red cells by bivalent antibody molecules<sup>10,11</sup>. The formation of such antibody cross-linkages would require both the presence of free as well as bound antigenic sites. One could, therefore, assume that under idealized conditions, such as would be found in the interaction of homogeneous antibody and cell populations, 50 per cent satura-

Fig. 3. Comparison of quantitative agglutination curves obtained with A Rh positive red cells obtained from four different individuals. Agglutination was obtained with a single anti-A serum (28) and a single anti-Rh<sub>0</sub> serum (1412). Papain-treated red cells were used only with the anti-Rh<sub>0</sub> sera

Fig. 4. Comparison of quantitative agglutination curves obtained with cells possessing different numbers of antigenic sites per cell. Aliquots of tanned human group O red cells were coupled with different concentrations of human 7S  $\gamma$ -globulins. Agglutination was obtained with a rabbit anti-human  $\gamma$ -globulin serum.

Fig. 5. Comparison of quantitative agglutination curves obtained with  $A_1$  and  $A_2$  human red cells. Two anti-A sera giving dissimilar results are shown.

tion of the antigenic sites would provide the maximum opportunity for antibody cross-linkages to be formed. It could also be assumed that above or below 50 per cent saturation there would be a proportional decrease in the opportunity for intercellular linkages and, as a consequence, a proportional decrease in the intercellular binding force. However, the magnitude of the intercellular binding force achieved between cells would be determined not only by the proportion of free and bound antigenic sites, but also by the stability and absolute number of the intercellular linkages formed. It is on the basis of the last-mentioned two parameters that antibody heterogeneity and variation in number and strength of the antigenic sites find expression in the prozone phenomenon.

The stability of the antibody linkage formed between cells is basically determined by the chemical and structural complementarity between the antigen and antibody combining sites<sup>12</sup>; the greater the degree of complementarity the more stable their union. Antibody molecules with the same antigenic specificity may vary widely in their binding strengths, even to the simplest of antigenic determinants<sup>13</sup>. As a consequence of this heterogeneity, antibody molecules of different binding strengths may be represented in given antisera in different proportions and concentrations<sup>9</sup>. In general, an antiserum composed of

more weakly binding antibody molecules would require a greater number of antigen-antibody linkages/cell to achieve a specific percentage agglutination than would be required by an antiserum composed of more strongly binding antibody molecules. Therefore, in terms of the quantitative agglutination curve, agglutination with a weakly binding antiserum would occur over a narrower range of antiserum concentrations than would be found with a more strongly binding antiserum. Correspondingly homogeneous antibody populations, with respect to their binding properties, could be expected to give symmetrical curves, whereas heterogeneous antibody populations could be expected to give agglutination curves with varying degrees of skewness and secondary peaks, dependent on the particular composition of the individual antibody population. These qualitative and quantitative differences would account for the dissimilarity in the quantitative agglutination curves shown in Fig. 2.

Blocking antibodies and their role in the prozone phenomenon<sup>14</sup> can be considered to represent one aspect of antibody heterogeneity. These antibodies can be broadly defined as antibody molecules capable of combining with the antigenic sites of a given cell population, but unable to form sufficiently stable intercellular linkages to result in agglutination. This would require one or both of the combining sites of a bivalent antibody molecule being deficient<sup>15</sup>. Such blocking antibody molecules may represent a major portion of an antibody population, as is found with the majority of human Rh antisera, or they may constitute only a small fraction of the total antibody population. Blocking antibodies, in a mixture of blocking and agglutinating antibodies, would effect agglutination by combining with available antigenic sites and prevent the combination of those antibody molecules capable of producing agglutination<sup>9</sup>. This would have a total practical effect of reducing the available number of antigenic sites/cell. Those antisera containing a higher proportion of blocking antibodies would have a more pronounced prozone, similar to the effect resulting from a direct reduction in the number of antigenic sites/cell (Fig. 4).

The expression of blocking activity, however, is not an independent characteristic, but rather highly dependent on the cell population used for testing. This was inferred in our definition in which blocking antibodies were defined in terms of their reaction with a 'given' cell population. This was necessary because antigenic properties and, therefore, agglutinating properties may differ from one cell population to another<sup>16</sup>. Such antigenic differences may be so extreme that an antiserum can be agglutinating with one cell population, blocking with another and unable to combine with a third<sup>17</sup>.

Antigenic differences between cell populations can be due to a difference in the number of antigenic sites/cell or, as well, to a difference in the binding properties of the antigenic sites. In terms of the agglutination reaction, the effect of these two factors would not be distinguishable. Within limits, it could be expected that an increase in the number of antigenic sites/cell would compensate for a deficiency in their binding strength and vice versa. The comparison of different cell population with a single antiserum (Fig. 3) showed the accumulative effect of antigenic differences resulting in characteristic agglutination curves, whereas in Fig. 4 the effect of purely quantitative differences in the number of antigenic sites/cell was illustrated. Finally, the combined effect of antibody heterogeneity and antigenic variation was evident in the comparison of the agglutination curves obtained with  $A_1$  and  $A_2$  cells shown in Fig. 5.

In summary, the ability to demonstrate a prozone with most of the antisera examined indicates that it is not a phenomenon of rare occurrence, but rather a basic phase of the agglutination reactions associated with antibody excess. It was concluded that the prozone phenomenon is, as it has been traditionally considered to be, primarily caused by antibody molecules occupying too great a

proportion of the available antigenic sites. This was considered to result in a mechanical deficiency in the number of antibody linkages formed between cells and, as a consequence, a reduction in agglutination. Contributing to this phenomenon are the factors which determine the stability and absolute number of intercellular linkages. Variation in the slopes of the quantitative agglutination curves in antibody excess was indicative of the heterogeneity found within and between antibody populations. Correspondingly, the differences in quantitative agglutination curves found when different cell populations were compared reflect the contribution of antigenic properties of the cell to the haemagglutination reaction in general and the prozone phenomenon in particular.

## SMALL-ANGLE ELECTRON DIFFRACTION PATTERNS OF ASSEMBLIES OF SPHERES AND VIRUSES

By JANET SMART and PROF. R. E. BURGE

Department of Physics, Queen Elizabeth College (University of London), London, W.8

THE technique of small-angle electron diffraction introduced by Mahl and Weitsch<sup>1</sup> has since been used in investigations of the structure of polyethylene<sup>2</sup>, the scattering by ferromagnetic films<sup>3</sup>, and the structure of catalase<sup>4</sup> as outlined by the negative staining method<sup>5</sup>. It is the purpose here to show the value, in relation to biological specimens, of experiments similar in outline to those carried out by Mahl and Weitsch on specimens made up of particles of either evaporated metal or inorganic salts. Specimens which we have examined so far include polystyrene latex spheres (a useful organic test specimen) and the tobacco necrosis and turnip crinkle polyhedral viruses.

Specimens were prepared for electron microscopy by depositing droplets of the particle suspensions in distilled water on supporting grids covered with thin films of evaporated carbon. The final particle concentrations on the grids could readily be varied. In regions of high particle density, in favourable cases, two-dimensional paracrystalline lattices formed. In an ideal experiment, as the particle density was progressively reduced, the degree of ordering of the arrays would vary from the paracrystalline through a liquid-like state (in two dimensions) until the particles were randomly distributed in the specimen plane. (A random distribution would effectively occur when all the interparticle distances were much greater than the resolving power of the diffraction arrangement.) The specimens were examined in an Associated Electrical Industries E.M.6 electron microscope under similar small-angle electron diffraction conditions to those described by Ferrier<sup>6</sup>. The diffraction camera length (C.L.) used was about 60 m for electrons of 80-keV energy. The resolution in the diffraction pattern depends primarily on the size of the incident electron beam at the specimen (about 10  $\mu$  in this work) and the magnification chosen for the second projector lens. Under the conditions adopted, reflexions corresponding to Bragg diffraction angles  $\geq 3 \times 10^{-5}$  radians (or Bragg planes of spacing  $\leq 1350$  Å) could be recorded photographically. Exposure times were normally in the range from 5 to 30 sec. None of the specimens gave observable (above background) coherent diffraction corresponding to spacings less than about 60 Å.

In Figs. 1a-d are shown examples of small-angle patterns from paracrystalline arrangements of polystyrene spheres and tobacco necrosis virus, a liquid-like

distribution of turnip crinkle virus, and a random arrangement of polystyrene spheres. In all cases the coherent features of the patterns appear superimposed on an intense background photographic density due to the electrons elastically and inelastically scattered by the supporting film and the incoherent scattering by the particles themselves.

Normal transmission electron microscope observations of the specimen regions giving rise to the diffraction patterns (a) and (b) showed that the basic crystalline arrangements in the paracrystals were hexagonal but that many stacking faults were present together with other lattice distortions. If the paracrystalline reflexions are interpreted as the  $h\bar{h}k + k$  0 reflexions of an infinite hexagonal lattice and a geometrical calibration<sup>3</sup> of the diffraction camera length is used, then the following values for the mean interparticle separations are obtained: polystyrene latex spheres  $880 \pm 20$  Å; tobacco necrosis virus  $192 \pm 3$  Å. These values are in agreement with diameter measurements made by transmission microscopy using gold-palladium shadowed specimens.

The mechanism by which the reflexions arise from the paracrystals is intermediate between the mechanisms in X-ray and optical diffraction. In X-ray specimens each particle forms part of a three-dimensional assembly and each particle scatters X-rays in three dimensions. In the optical analogue to X-ray diffraction<sup>6</sup> the diffraction pattern is formed by combining the light transmitted through holes in a two-dimensional screen. In the electron diffraction patterns, electrons are scattered elastically (or effectively elastically) throughout the volume of each particle and are subject to similar phase relationships to those found in the X-ray case (that is, the Fourier transforms of the (dehydrated) particles are of the same form for electrons as for X-rays), but the lattices are two-dimensional. The limited number of reflexions from the paracrystals thus provide some information about the spherically averaged Fourier transforms of the polystyrene or virus particles since the paracrystalline patterns may be regarded as (rather poor) lattice samplings of these transforms.

The angular extents of the coherent patterns in Figs. 1a-c give an indication both of the linear extents of the regions of ordered packing of the particles and of damage to the specimen caused by the electron beam. In the specimens of turnip crinkle virus no regular arrangements of more

Fig. 1. Small-angle electron diffraction patterns (80 keV electrons) of: (a) Paracrystalline assembly of polystyrene latex spheres. Diffraction camera length as printed  $C.L.=92$  m. (b) Paracrystalline assembly of tobacco necrosis virus particles.  $C.L.=27$  m. (c) Liquid-like assembly of turnip crinkle virus particles.  $C.L.=92$  m. (d) Random assembly in two dimensions of polystyrene latex spheres.  $C.L.=71$  m.

than 1000 Å in linear extent were observed and consequently the turnip crinkle pattern (Fig. 1c) is similar to that expected from a statistical particle arrangement as found in a liquid<sup>7</sup>. The single ring at a spacing of  $308 \pm 10$  Å represents the interparticle distance which occurs with maximum probability, that is, the mean particle diameter. This value is again in reasonable agreement with the value found by transmission electron microscopy. It has not, so far, been found possible by changing the particle concentration in the specimens of turnip crinkle virus to obtain a paracrystalline pattern. However, a liquid-like diffraction pattern from tobacco necrosis virus has been observed.

Using low particle densities in specimens of polystyrene spheres we have directly photographed the continuous Fourier transforms arising in effect from single spheres. Such a pattern for spheres of mean diameter 880 Å is shown in Fig. 1d; similar patterns have been obtained for 1260 Å diameter spheres. The positions and relative intensities of the diffraction rings in Fig. 1d correspond closely to those expected from the expression for the transform of a sphere of the known radius<sup>8</sup>. Similar, but less extensive, information on Fourier transforms can also be found by the rather tedious and lengthy methods

of small-angle X-ray diffraction applied to extremely dilute particle suspensions<sup>9</sup>. The electron diffraction method, besides having advantages in greater angular range and speed of recording the patterns, has the further advantage that each pattern refers to a definable group of particles for which the polydispersity of size (and to some extent shape) can be measured from electron micrographs; its main disadvantage is that the continuous transform is superimposed on a high background intensity of incoherently scattered electrons. The last factor, even for specimens undistorted by the electron beam, sets a lower limit to the particle diameters for which 'random' patterns (with the implied large interparticle distances) are observable even with the thinnest specimen supporting film.

It may be noted that the angular extents (regardless of exposure time) of the coherent diffraction patterns of the type shown in Fig. 1d are greater than those characterized by Fig. 1a. This indicates that the blurring of the continuous particle Fourier transform due to the polydispersity of the particle diameters is less than the blurring of the discontinuous lattice transform due to the distribution of interparticle separations in the paracrystals. The Fourier transforms of isolated virus particles have not yet been satisfactorily observed; a difficulty of specimen preparation is that when the viruses are in a suitable concentration for observable diffraction they tend to clump on the specimen grids and the clumps give rise to very weak liquid-like diffraction patterns.

Emphasis has been given here mainly to the observational aspects of the small-angle electron diffraction patterns from particle assemblies in the absence of any deliberate attempts to crystallize the specimens on the supporting film. However, an examination of the intensities of the reflexions from viruses and other assemblies is of interest both because of the structural information that may be derived from it (especially from crystalline rather than paracrystalline specimens) and from the point of view of the theory of small-angle electron diffraction; both these aspects are being investigated.

We thank Dr. R. P. Ferrier for his advice. The virus specimens were supplied by Mr. H. L. Nixon and Dr. B. Kassanis. One of us (J. S.) thanks the Department of Scientific and Industrial Research for a maintenance award.

## •✓ READING RATE, WORD INFORMATION AND AUDITORY MONITORING OF SPEECH

By DR. ANNE M. TREISMAN

Psycholinguistic Research Unit, Institute of Experimental Psychology, University of Oxford

DURING the past twelve years there has been a great deal of research on the part played by auditory feedback in the control of speech production. Lee<sup>1</sup> first showed that if subjects were allowed to hear their own voices only with a delay of about 0.2 sec, their speech was

remarkably disrupted. They stuttered, stammered, drawled or broke down completely. Since then many people have worked on more detailed aspects of the breakdown, such as the different effects on vowels and consonants<sup>2</sup>, on vocal rate and intensity<sup>3</sup>, and on articulation<sup>4</sup>.

and the effects of variation in the length of the delay<sup>5</sup>. At what level is the auditory feed-back monitored? Lee suggested that it primarily controls the 'voice loop' producing syllabic units. Chase<sup>6</sup> showed that delaying the feed-back can facilitate the repetition of a single sound or phoneme 'b', and Fairbanks and Guttman found that the majority of errors were one phoneme long. However, the problem is unlikely to have a single, simple solution. Fairbanks showed that the type of disturbance varied with the delay interval used, and concluded that the "units of speech control should not be identified with any of the conventional units such as the phoneme". Control may be at many levels from phonation and articulation to whole phrase or sentence.

Little of the work so far has investigated control at the highest level. This problem could be tackled by varying the information rate in the words of different passages, and using them in delayed feed-back reading tests. If any monitoring were carried out at the high level of word or phrase, delayed feed-back might be expected to produce variations in disturbance with passages of differing redundancy, while the control of the simpler motor elements of phonation and articulation would be unaffected, since while verbal information varies, phonetic information remains the same. One might be able to separate out the different components of the total reading time in normal conditions and with delayed feed-back by comparing reading rates under these conditions with those obtained in silent reading and in reading aloud with auditory feed-back completely masked by noise.

The passages used in the experiment reported here were a set of statistical approximations to English<sup>7</sup> prepared in the manner described by Miller and Selfridge<sup>8</sup>. The set included a 1st-, 2nd-, 4th-, 6th- and 8th-order passage and a passage of normal prose taken from Conrad's novel *Lord Jim*. Each was 100 words long and typewritten without punctuation on a separate sheet of paper. Estimates of the information content of these passages were made by taking  $\log_2 p$  of the probabilities estimated from the frequencies with which two samples of 10 missing words from each passage were correctly replaced by two groups of 100 subjects<sup>9</sup>. These missing words were deleted at regular intervals of one word in ten, chosen to be at the asymptote where predictability does not increase with increased context or decreased deletion rates. The values obtained were 4.8, 3.9, 3.6 and 3.3 bits for 2nd-, 4th-, 6th- and 8th-order approximations respectively, and 2.6 bits for a prose extract from Conrad's novel *Lord Jim*. The 1st-order passage was a random selection of words from a novel and the mean information per word was taken from the frequencies of the twenty missing words given in the Thorndike-Lorge word count<sup>10</sup>; the value was 9.2 bits.

There were five groups of subjects (all university students or graduates), each of whom read the passages under a different condition. Within each group the order in which the passages were given was randomized. Group A (12 subjects) read them aloud at a natural speed; Group B (12 subjects) read them silently at a natural speed; Group C (11 subjects) read them aloud while a loud masking noise was played over headphones to both ears; Group D (7 subjects) read them backwards as quickly as possible, starting with the last word and working back from right to left along the lines to the first word; Group E (21 subjects) read the passages aloud with delayed auditory feed-back. Their speech was recorded and played back about 0.25 sec later at a high intensity to both ears over headphones. This group was first given one passage of normal prose to read, to introduce them to the delayed feed-back. In Group E a clear division between two types of subjects emerged: one sub-group of 9 subjects was not affected at all by the delayed feed-back and their results did not differ from those of Group A; the other sub-group of 12 subjects showed the typical disturbances reported in the literature—slowing

up, drawing, stammering and so on. The results of these two groups were analysed separately. The criterion for assigning subjects to the latter group was that their mean time for reading a passage with delayed feed-back should be more than 40 sec. The mean for Group A was 35.4 with a range of 28.5–41.2 sec. The mean for subjects in Group E who showed no overt disturbance was 36.5 sec.

Each experiment was recorded and the time taken to read the passages was measured. Fig. 1 shows the mean time per word plotted against the average information per word in the different passages. Results of an experiment by Morton<sup>11</sup> are also included: his subjects (also university students) read a set of approximations aloud as quickly as possible. The regression for subjects in Group E, who were unaffected by the delayed feed-back, is not shown as there was no significant difference between this and the regression for Group A. The equation was  $T = 1.52 \text{ Inf.} + 29.6$ . All the regression co-efficients are significant except that for reading backwards which is quite insignificant, and the departures from linearity are not significant in each case. The only significant differences in slope of the regressions are between the delayed feed-back condition and the others, and the reading backwards and the others. The delayed feed-back regression is significantly steeper than the regression for normal reading aloud ( $P < 0.02$ ), and the regression for reading backwards is significantly less steep ( $P < 0.001$ ). Thus the difference between silent reading, rapid reading aloud (Morton's results) and normal reading aloud is a difference in the constant component of the reading time

Fig. 1. Reading times and word information

rather than in the component which varies with verbal information content. The delayed feed-back, on the other hand (for those subjects who were affected), halved the rate of gain of information as well as increasing the intercept.

What do these results imply about the different factors contributing to total reading time? The fact that the time taken to read the passages backwards was constant shows that the variation in the other conditions must be due to the varying information content resulting from the sequential dependencies between words, and not to differences in word length or difficulty. It seems plausible to divide the total time into two main components, which may or may not overlap in practice: (I) the perception time taken to read the passage; (II) the time taken to organize and perhaps to monitor the response. Each of these may be composed of (a) a verbal component which varies with the information content of the words, and (b) a non-verbal component independent of word information. For (I), the visual input, one can distinguish (a) the information taken from the verbal context; (b) that taken directly from the print. The latter visual discrimination factor would be constant for all passages, while the former would vary with information content. For (II), the vocal output, (a) the variable component might be the selection and perhaps the monitoring of responses at the level of word or phrase, while (b) the constant component was the control of the mechanics of articulation.

The silent reading condition probably reveals the effect of the input component only. The constant of 17.1 sec could reflect the visual discrimination time, while the slope shows the information component and implies the high rate of gain of 68 bits of information per sec. Normal reading aloud makes no significant change in the information component, but it adds a constant of 10.6 sec to all passages, which, in terms of the account given here, would be the time taken for the control of articulation. The fact that the slope does not change shows that the information time hypothesized for response selection cannot be independent of the information time required to identify the input. It seems that, once the words or phrases have

been recognized, no further time is necessary at this level to select and organize the words as vocal responses. It also suggests that whatever monitoring of auditory feed-back is normally carried out does not require any extra information capacity. This is confirmed by the result from Group C who read aloud with noise: there is no significant difference in reading time between this condition and normal reading aloud, so that the absence of auditory feed-back has no effect on either component of the reading time. The instruction to read aloud as fast as possible again has no effect on the slope of the regression (if Morton's subjects and passages were comparable with the present ones). Subjects appear to be processing contextual information at the verbal level as fast as possible in normal reading; but they are able to reduce the constant component of the response time, either by shortening the time taken for articulation or by reducing the extent of monitoring at the non-verbal level. Fig. 2 illustrates these suggestions.

The account so far assumes that the informational and non-informational components of the total time are independent and do not overlap or mask each other, as did Crossman's choice and movement time in card-sorting when his subjects saw the cards in advance<sup>12</sup>. It seems *a priori* more likely that they should overlap in reading, since subjects can look ahead of the words they are speaking. The apparently very high rate of gain of information taken from the slope would then be an artefact. However, the fact that instructions (to read fast) and the presence or absence of vocalization affect the constant component without altering the information rate suggests that one is justified in treating the two components separately. If this way of measuring the information rate is valid, it gives an unusually high value—about 60–70 bits per sec. The usual finding in reaction time experiments is 5–7 bits per sec<sup>13</sup>; but it is interesting that in an auditory-verbal reaction task—repeating letters, numbers or nonsense syllables—Davis, Moray and Treisman<sup>14</sup> also obtained a rate of gain between 60 and 70 bits per sec, although they questioned whether this measure was meaningful. Both tasks involve a high degree

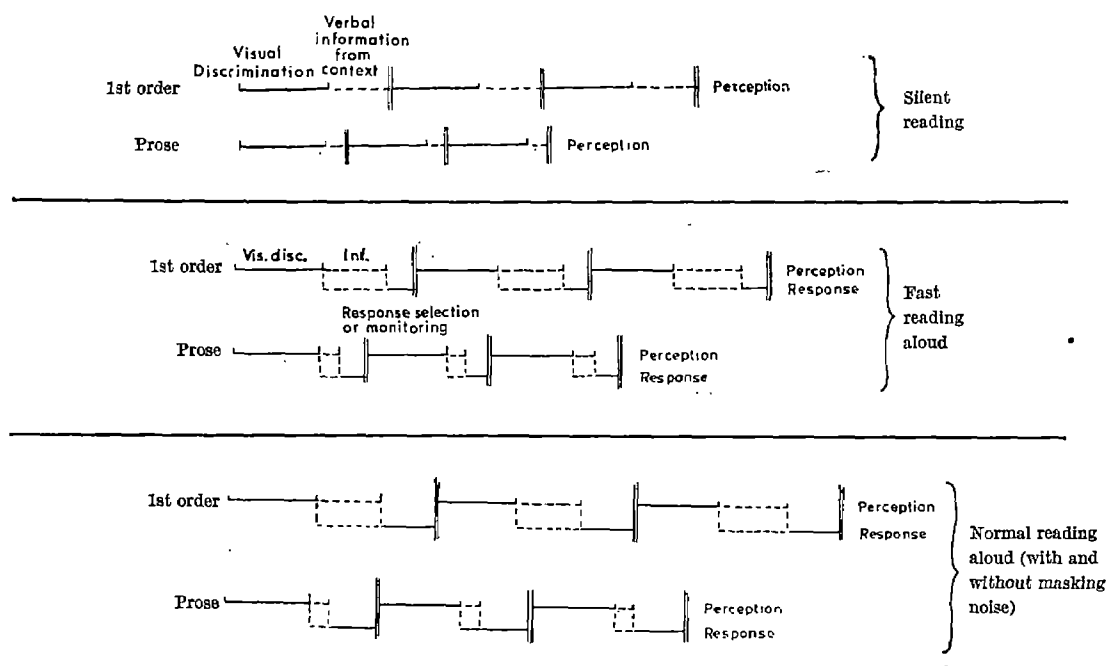

Fig. 2. Suggested components of reading time for passages of different information content. || Segments represent the time taken over a constant number of words; — components represent proportion of time for non-verbal information processing; - - - components represent proportion of time for verbal information processing. The order of the components between these || segments is arbitrarily chosen in the diagram. The lengths represent the proportion of time taken on each component, but the division between the two components may follow a different pattern.

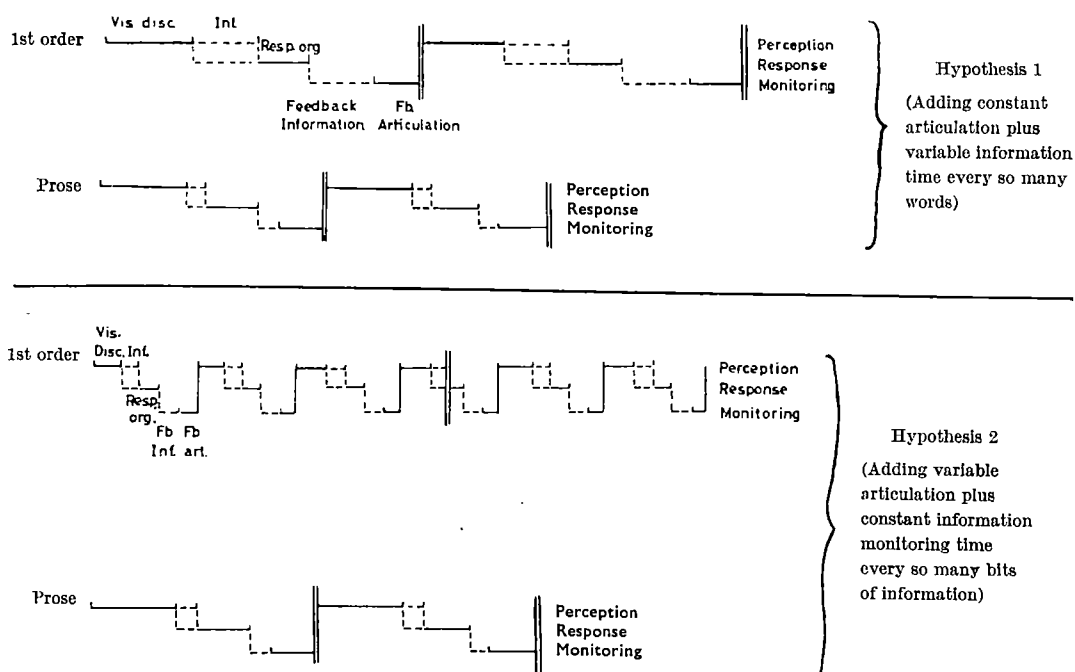

Fig. 3. Suggested components of reading time with auditory feed-back

of familiarity and 'stimulus-response compatibility', which might leave a large capacity available for transmitting information.

The introduction of delayed auditory feed-back is the only condition which affects the information rate as well as the constant component. The increase in the constant reflects the auditory monitoring at a non-verbal level. The most plausible explanation of the change in slope is that the feed-back is now monitored at the verbal as well as at the phonemic level. This might be because the delay in the feed-back causes a phonemic mismatch at the normal interval at which the vocal output and the feed-back are compared. The words in the feed-back thus become unpredictable and are treated as new information to be processed completely a second time; this increases reading time by doubling the slope and halving the rate of gain of information. The fact that the regression coefficient is approximately doubled agrees well with this hypothesis, but the factor of 2 is not crucial. It might be, for example, that at shorter or longer delays the slope would be less than twice as steep: this would be explained by the fact that the mismatch between vocal output and auditory feed-back was less disturbing and easier to ignore, so that only a proportion of the words were processed twice at the level of verbal information. If some other condition made the mismatch still more disturbing (for example, increasing the intensity of the feed-back), this might force subjects to process some words more than twice, so that the slope could be more than doubled. The crucial point for this hypothesis is that the slope should be steeper for delayed auditory feed-back than for other conditions.

Finally, one might distinguish two forms which the verbal monitoring could take: it might be that subjects monitor their speech every so many words—a fixed number for all passages—and that the monitoring adds a certain time which varies with the information content of the words; or alternatively the monitoring might be made every constant number of bits, so that it occurs more often for the incoherent than the coherent passages, but adds a constant component to the total reading time every time it is made. These suggestions are illustrated in Fig. 3. The results of four subjects were examined in

more detail to throw light on these alternatives. If monitoring were carried out at intervals which vary with the information content, one should expect to find the overt disturbances, such as lengthening and repetitions of sounds, also occurring at intervals which vary with information. The mean number of these per passage is given in Table 1. It reveals that, on the average, one correction or pause is made every four words for the 1st-order passage and every eight words for the prose. The interval does appear to vary with the coherence of the passage. This would be consistent with the idea that speech responses are organized or programmed in discrete segments which vary with the information content and which are monitored intermittently as wholes.

Passage	1st-order	2nd-order	4th-order	6th-order	8th-order	Prose
Mean number of repetitions, pauses or lengthened words per 100 word passage	25.3	22.5	19.0	19.3	18.8	12.3
Speech disturbance every how many words	4.0	4.4	5.3	5.2	5.3	8.1

Since this work was carried out, Fillenbaum has reported a similar experiment with different results (Fillenbaum, S., *J. Acoust. Soc. Amer.*, **33**, 1800, 1961). I am at present unable to explain the discrepancy.

## LETTERS TO THE EDITOR

## RADIO ASTRONOMY

## Occultation of the Crab Nebula by the Solar Corona at Centimetre Wave-lengths in June 1964

DURING the occultation of Taurus in June 1961 and 1962, centimetre wave-length observations were undertaken by U.S. Air Force Cambridge Research Laboratories scientists to investigate small-scale irregularities, if any, in the solar corona which might produce wide-angle scattering at metre wave-lengths and also be observed at centimetre wave-lengths. Results for 1962 were interpreted by Basu and Castelli<sup>1</sup> to indicate a progressive broadening of the source and a decrease in source intensity as the angular separation between Taurus and the Sun became smaller. The reverse tendency was noted on the egress part of the cycle. The broadened maximum extent of the source was found to be about 20 min of arc at  $\lambda = 10$  cm.

In 1964, using the identical technique as in 1962, no apparent broadening or change in source intensity was detected.

Observational wave-lengths were 25 cm and 10 cm. Equipment consisted of conventional radiometers and a single 84-ft. parabolic antenna with a dual frequency linearly polarized feed. The pencil beam produced was less than 17.5 min of arc at  $\lambda = 10$  cm and about 36 min at  $\lambda = 25$  cm.

The observing technique used in 1962 and again in 1964 was to make 4 or 5 right ascension drifts of the source and/or solar contribution each day between June 10 and 20. Then, on control days during the final week of June, drifts were taken with the antenna directed at points in the sky corresponding to the angular separation between the Sun and the radio source, Taurus, during the actual occultation period.

During the occultation period, temperature calibrations were made before and after each drift. Sufficient time was allowed for each drift to establish a far-out steady sky level free from solar contribution. On the control days, equipment gains were adjusted to agree with those on corresponding data days. This was done using noise generator calibrations.

The solar flux was found for each day both locally and by referring to the Ottawa 2,800-Mc/s flux, and control day drifts were effectively normalized to comparison days in respect to solar contribution through the antenna side lobes.

Finally, the actual curves and control day curves were subtracted from each other. We were careful to reference curves at far-out zero points. For each day's equipment gain settings, linearity was determined and corrections were made where applicable.

The actual response curves due to Taurus alone after subtraction of the solar component were constructed by plotting signal levels taken at 6-sec intervals from the analogue records. At  $\lambda = 10$  cm, points for plotting were read with an accuracy of  $\pm 1$  sec. Half-power widths of the constructed response curves were read with an accuracy of better than  $\pm 1.5$  sec of time.

The time-width of each constructed drift due to Taurus alone at half-intensity level was compared with drifts made early or late in June when there was no question of solar contribution in the response drift.

It is also possible (and this has been done) to compute the angular extent of Taurus whether unbroadened or otherwise from the expression:

$$C^2 = A^2 + B^2$$

where  $C$  = the actual source response where minutes of arc = (min of time)  $15 \cos$  declination;  $A$  = the actual antenna half-power beam width;  $B$  = the Gaussian source half-intensity width.

Theoretical maximum intensity calibration errors at  $\lambda = 10$  cm of  $\pm 3^\circ$  K due to precision variable attenuator resettability and absolute calibration over the operating range in the 10-cm equipment scarcely apply. Practically, by peak calibration of many drifts of various sources with the same equipment, it is felt that in the present case the maximum probable relative intensity error is under  $\pm 1.5^\circ$  K.

The validity of the whole method is based on the extraordinary stability of the antenna side lobes and on how well we are able to calibrate out the solar contribution.

Results are presented in Table 1.

Table 1

Date	1964 = 10 cm Source extent at half- intensity—min		Source temp. at receiver	Signal percentage solar
	Time	Arc		
June 3-5, control	1:275'	4:6'	—	0
June 11	1:25	3:1	24.7° K	17
June 12	1:25	3:1	23:8	18.8
June 13	1:275	4:6	23:72	50
June 14	1:275	4:6	24:04	57
June 15	1:29	5:4	23:71	17.8
June 16	1:25	3:1	24:68	14.3
June 17	1:275	4:6	24:8	15.9
June 26, control	1:275	4:6	23:8	0

Uncertainty: time duration of drift half-intensity—3 sec. Angular extent of source possible error 2.8 min of arc. Intensity uncertainty limits  $24^\circ \pm 1.5^\circ$  K.

In 1963, other observers have detected no significant broadening at 6, 13, 18 and 21 cm. Air Force Cambridge Research Laboratories personnel did not repeat the 1962 measurements in the same form. Therefore, we can only assume that the 1963 evidence of others is correct for 1963. In view of the results of the present 1964 investigation, which seems to justify the method, an explanation is sought for our 1962 results. Such an explanation is not to be found in a comparison of the fluxes for the various days and years. However, it is significant that, in 1962, an active region was present at about  $10^\circ$  south of the solar equator. It is the southern corona which is probed by the measurement at the time of minimum angular separation of the Sun and Taurus. At the Union Radio Scientifique Internationale General Assembly in Tokyo, Japan, in 1963, Vitkevich commented on an unusual scattering effect observed on June 10, 1962, at metre wave-lengths and lasting for several hours.

It is anticipated that similar investigations will be continued in the coming year.

## ASTRONOMY

## Lunar Luminescence

In a recent article, Kopal<sup>1</sup> has directed attention to a report by Sir William Herschel<sup>2</sup> of 'volcanoes' in the neighbourhood of the lunar crater Aristarchus seen in April of 1787. Both he and Middlehurst<sup>3</sup> note the similarity between Herschel's description and two recent reports by Greenacre<sup>4,5</sup> of reddish luminescence near Aristarchus in October and November 1963. In Table 1 are listed 16 additional transient luminescent events in the vicinity

of Aristarchus observed during the period 1783–1963. Included in the second column of Table 1 are the colour, the visual magnitude, and the dimensions of those luminescent spots for which these data were reported. Of the 19 observations listed, the first 16 were made 2–6 days after new Moon; that is, when Aristarchus was on the dark side of the lunar surface far from the terminator. The three most recent observations were made shortly after full Moon, with the crater in sunlight. In addition to these reports, the literature contains references to luminescent events in the vicinity of several other lunar features including Pitatus<sup>23</sup>, Heraclides Promontory<sup>24</sup>, Alpine Valley<sup>25</sup>, Carlini<sup>26</sup>, Alphonsus<sup>27</sup>, and Kepler<sup>28</sup>. All these events, except those involving Alphonsus and Kepler, were on the dark side of the Moon. The latter two events as well as the luminescence of Aristarchus observed by Kozyrev<sup>22</sup> in 1961 were recorded photographically. Several of the remaining events were observed visually through different telescopes by two or more independent observers.

Table 1. OBSERVATIONS OF LUMINESCENCE IN THE VICINITY OF ARISTARCHUS

Date of observation	Description	Observer and ref.
May 4, 1783	Red; fourth mag.; < 3 in. arc	Herschel <sup>6</sup>
April 19–20, 1787	Red; < fourth mag.; 3 in. arc	Herschel <sup>12</sup>
March–May, 1789		Bode <sup>7</sup>
Feb. 4–7, 1821	Sixth–seventh mag.; 3 in.–4 in. arc	Kater <sup>8</sup>
May 4–6, 1821	< 1 in. arc	Obers <sup>9</sup>
Jan. 27, 1822	Eighth mag.	Ward <sup>10</sup>
May 1, 1824	Ninth–tenth mag.	Baily <sup>11</sup>
April 22, 1825	—	Struve <sup>12</sup>
Dec. 25, 1832	—	Göbel <sup>13</sup>
Dec. 22, 1835	—	Argelander <sup>14</sup>
Jan. 14–16, 1866	Ninth–tenth mag.	Göbel <sup>15</sup>
April 9, 1867	Reddish-yellow	Smyth <sup>16</sup>
May 7, 1867	Seventh mag.	Smyth <sup>16</sup>
March 1–3, 1903	Reddish-yellow	Temple <sup>17</sup>
Feb. 22, 1931	Reddish-yellow	Elger <sup>17</sup>
March 30, 1933	White	Temple <sup>18</sup>
Nov. 26, 28, Dec. 3, 1961	Red and blue	Rey <sup>19</sup>
Oct. 29, 1963	Reddish-orange to light ruby	Gheury <sup>18</sup>
Nov. 27, 1963	Light ruby	Joula <sup>20</sup>
		Douillet <sup>21</sup>
		Kozyrev <sup>22</sup>
		Greenacre <sup>4</sup>
		Greenacre and Boyce <sup>5</sup>

Kopal and Rackham<sup>28</sup> have proposed that the luminescence observed by them in the vicinity of Kepler was excited by streams of corpuscular radiation emanating from a solar flare. Accordingly, Kopal<sup>1</sup> suggests that the luminosity of Aristarchus seen in 1787 as well as in 1963 was likewise due to flare-accelerated particles directed to the crater by interplanetary magnetic fields. In support of this suggestion, he notes that May of 1787 was the peak of an unusually active solar cycle. It therefore seems worthwhile to consider the distribution of the events in Table 1 with respect to solar activity:

Yearly mean sunspot No.	No. of events
0–30	15
30–60	2
60–90	0
90–120	1
120–150	1

Clearly, the 19 events are negatively correlated with solar activity. This fact alone does not necessarily eliminate solar flares as a cause of the luminescence, since major flares have occurred, although infrequently, very near solar minima.

Unfortunately, flare records are incomplete before the last few solar cycles; but none of the flares reported<sup>29</sup> can be associated with the first 16 events in Table 1. Of the remaining three events, only one followed a major flare. This was the first emission observed by Greenacre, which followed by two days the largest flare (Class 3) of 1963. The second event seen by Greenacre a month later, on the other hand, occurred during a period in which the Sun was exceptionally inactive. The three luminescent

emissions reported by Kozyrev—which he, like Herschel, attributed to volcanic activity—fell during a period in which no flares larger than Class 1, and no high-energy solar particle radiation, were recorded. On the basis of this review, then, it appears that luminous spots in the vicinity of Aristarchus are not directly associated with particle radiation from solar flares.

A more quantitative objection to the excitation mechanism proposed by Kopal concerns the radiant energies required to produce the observed red spots. As shown in Table 1, the spots seen on the dark side of the Moon were estimated to vary in brightness from 10 to 4 stellar magnitudes, corresponding to luminous fluxes at the lunar distance of  $10^{13}$ – $10^{16}$  ergs/sec. The areas involved were a few seconds of arc or less, corresponding to dimensions of kilometres. Hence, the radiant energies associated with the spots were of the order of  $10^3$ – $10^6$  ergs/cm<sup>2</sup> sec. Derham and Geake<sup>30</sup> have demonstrated that certain achondritic meteorites luminesce in the red when bombarded with 40-keV protons, the particle energy being converted to light quanta with an efficiency of approximately 20 per cent. Assuming a comparable efficiency for the excitation of lunar luminescence by solar particles, corpuscular streams carrying from  $5 \times 10^3$  to  $5 \times 10^6$  ergs/cm<sup>2</sup> sec to distances of 1 A.U. are required. In order to direct the solar particles to the dark side of the Moon, Kopal postulates that their radius of gyration in the interplanetary magnetic field is large compared with the lunar diameter. Such particles must have energies close to 10 MeV or greater in an interplanetary field of 10γ, taken by Kopal as the average value. The largest particle flux above 10 MeV observed at the Earth so far, corrected for atmospheric absorption and for geomagnetic screening, is somewhat less than  $10^8$  per cm<sup>2</sup> sec (ref. 31). With a mean particle energy of 40 MeV, this particle flux corresponds to an energy flux of less than 3 ergs/cm<sup>2</sup> sec. These figures apply to the peak of the particle event following the 3+ flare of November 12, 1960. Thus, even for the largest event on record, the energies carried to 1 A.U. by solar corpuscular radiation above 10 MeV are only a few ergs/cm<sup>2</sup> sec, from 3 to 6 orders of magnitude too small to account for the emissions listed in Table 1. The solar wind, proposed as an alternative source of lunar luminescence, likewise carries energies of only a few ergs per cm<sup>2</sup> sec at 1 A.U. during peak solar activity. In fact, the entire spectrum of charged particles observed in interplanetary space, integrated over energy and including galactic as well as solar components, has peak intensities well under 100 ergs/cm<sup>2</sup> sec. This is less than the energy of the 'Earthshine', which has been suggested as the source of the phenomenon seen by Herschel. It is also three orders of magnitude too small to account for the luminescence near Kepler observed by Kopal and Rackham<sup>28</sup>.

In summary, luminous emissions, usually reddish in colour, occur in the neighbourhood of the crater Aristarchus whether or not the crater is in sunlight and whether or not the Sun is active. Neither electromagnetic nor charged particle radiation in interplanetary space provides sufficient energy to produce the luminescence by direct excitation unless the flux over a large area is focused on the Moon. Alternatively, the flux might be stored over time to provide sufficient energy for the short-lived lunar emissions. Thus, focusing and/or storage appears to be a necessary feature of any model which attributes lunar luminescence to external energy sources.

Flamm and Lingenfelter are right in pointing out that the flux of particles accompanying solar events, as recorded so far by ground-based (or Earth-bound) experiments, are too low to provide adequate source of excitation for the visibility of daytime luminescence of the lunar surface; for night-time events it is adequate. Whether or not this is so at the distance of the Moon (that is, sufficiently far from the terrestrial magnetosphere) and in all parts of the energy spectrum remains, however, yet to be seen. Possibly the primary solar particles act only as a trigger of the lunar events<sup>1</sup>. The electromagnetic spectrum of the Sun contains ample energy for excitation; but its responsibility for transient lunar luminous phenomena seems to be contradicted by the time-lag, from several hours to a few days, indicated by the observation.

The stellar magnitudes assigned to lunar night-time events by early observers listed in Table 1 lack quantitative meaning; for no one could make photometric measurements at that time; and the definition of stellar magnitude in use to-day goes back only to 1850 (Pogson). Suffice it to say here that one square second of earthlit lunar surface would appear as a star of +13.5 vis. magn.; and the doubling of its brightness by luminescence would reduce it to only +12.7 magn. An area of 10 square seconds (comparable in size to Herschel's "volcanoes") would then appear as a star of 10.2 magn.

The existence of a positive correlation between solar inactivity and lunar events claimed by Flamm and Lingenfelter would—if confirmed—only deepen the problem, but the residual brightness of eclipsed Moon was found by Danjon<sup>2</sup> (1920) also to change abruptly at the time of the minimum (rather than maximum) of solar activity. At present it should be merely noted that both most conspicuous instances on record of transient lunar luminous phenomena (that is, the Greenacre-Barr and Kopal-Rackham flare-ups of October 30–November 2, 1963; and the Herschel flare-up of April 19–20, 1787) occurred at a time when the Sun was strongly disturbed. No flare observations are available, to be sure, for 1787; but the fact that the Sun must have been greatly disturbed

is attested by the visibility, on both days, of polar aurorae as far south as Padua, Italy<sup>3</sup>.

## GEOLOGY

### Carbon Isotope Composition of Individual Hydrocarbons from Italian Natural Gases

SINCE the fundamental paper by Craig<sup>1</sup> on the geochemistry of the stable carbon isotopes, much work has been done on the determination of carbon isotope distribution in different materials.

It was found<sup>1,2</sup> that the  $^{13}\text{C}/^{12}\text{C}$  ratio of methanes from natural gases ranges from  $-10.4$  per mil to  $-84.4$  per mil in  $\delta$  units. ( $\delta$  Carbon-13 is determined as follows:

$$\delta^{13}\text{C} = \left[ \frac{(^{13}\text{C}/^{12}\text{C})_{\text{sample}}}{(^{13}\text{C}/^{12}\text{C})_{\text{standard}}} - 1 \right] \times 1,000$$

Results are referred to the PDB standard (ref. 1).) This range of variation is the widest observed within a single class of carbonaceous materials.

Silverman<sup>3</sup> has recently reported the  $^{13}\text{C}/^{12}\text{C}$  ratios of individual light hydrocarbons separated from petroleum by fractional distillation. He showed that ethane and propane are about 11 and 13 per mil isotopically heavier than the associated methane. Apart from these data, referred to a single crude oil,  $^{13}\text{C}/^{12}\text{C}$  ratios relative to ethane, propane and higher hydrocarbons from natural gases are hitherto missing from the literature, in spite of their obvious geochemical importance.

We have developed an experimental technique, based essentially on gas chromatography, which enables the quantitative separation of individual carbon compounds from natural gases. Each hydrocarbon is converted to carbon dioxide, which is then analysed for the  $^{13}\text{C}/^{12}\text{C}$  ratio using a mass spectrometer equipped with double collector. Reproducible results are thus obtained, with an overall accuracy of  $\pm 0.3$  per mil. This technique was applied to the examination of natural gases from nine producing fields, located in southern Italy and Sicily. The chemical composition of such gases was also determined by gas chromatography.

The  $^{13}\text{C}/^{12}\text{C}$  ratio of methane ranges from  $-37.8$  to  $-71.5$   $\delta$  units in a total of 52 samples analysed. It was found that the carbon-13 content of methane decreases with increasing molar ratio  $\frac{\text{methane}}{\text{total hydrocarbons}}$  in the gases.

This trend (Fig. 1) is exhibited by all the samples examined, which were collected from different Italian gas fields.

As expected, ethane, propane and butane hydrocarbons are isotopically heavier than the associated methane. The results reported in Table 1 indicate that the ranges of  $\delta$  carbon-13 for such hydrocarbons are much narrower than that for methane.

The isotopically lightest Italian methanes fall in the same  $\delta$  carbon-13 range as other methanes of alleged bacterial origin<sup>2,4</sup>. Their  $\delta$  carbon-13 values indicate a probable depletion in carbon-13 of approximately 40–50 per mil with respect to the original organic matter.

The isotopically heaviest, among the Italian methanes analysed, are associated with relatively large amounts of ethane, propane and higher hydrocarbons. These heavier methanes indicate probable depletions not greater than 20 per mil, in agreement with the results obtained by Silverman<sup>3</sup> for a methane allegedly produced in the 'maturation' of petroleum.

Therefore, the trend of Fig. 1 could be explained by assuming that each gas results from the admixture of an

Fig. 1. Carbon isotopic analysis on methane from Italian natural gases. Ages of host-rocks: fields A, D, F, H = Pliocene; fields B, C, G = Miocene; field E = Cretaceous; field I = Triassic

isotopically lighter bacterial methane, and of a heavier methane produced with its homologues in a chemical process similar to the 'maturation' of petroleum.

As an alternative hypothesis to explain the trend of Fig. 1, it could be assumed that the wide isotopic range observed in methanes is essentially due to a fractionation, in the course of the migration, of the natural gases from the source of the reservoirs. Migration should thus be regarded as a complex process, which on one hand causes the segregation of each hydrocarbon and non-hydrocarbon component of the gas according to its mobility, and on the other hand gives rise, within each molecular species, to an isotopic fractionation, the extent of which depends on the molecular mass of the component itself.

Table 1. CARBON ISOTOPIC COMPOSITION OF INDIVIDUAL HYDROCARBONS FROM ITALIAN NATURAL GASES

Sample No.	CH <sub>4</sub>	C <sub>2</sub> H <sub>6</sub>	C <sub>3</sub> H <sub>8</sub>	C <sub>4</sub> H <sub>10</sub>
1	-47.7	-30.5	-26.5	-23.4
2	-57.6	-32.2	-26.4	-22.7
3	-59.5	-33.1	-27.0	-25.3
4	-57.6	-32.5	-27.5	
5	-52.9	-32.3	-25.3	
6	-41.1	-30.2	-26.0	
7	-46.4	-31.9	-25.2	-22.8
8	-48.4	-29.6	-25.3	-22.6
9	-56.9	-31.0	-26.1	

This latter hypothesis is corroborated by the isotopic data obtained on 17 methane samples from a single relatively small multi-horizon gas field in southern Italy, where a regular variation of  $\delta$  carbon-13 values as a function of depth was established, with an over-all range of 4.3  $\delta$  units.

Laboratory experiments were performed, in order to measure the isotopic fractionation of methane during chromatographic flow through a column filled with hydrogen-bentonite. Pure methane samples were allowed to flow, in a current of oxygen, through a column 20 m long at a temperature of 25° C with a pressure gradient of 2 atm. A Perkin-Elmer '154 B Vapor' fractometer was used, by which it was possible to split each sample of methane coming through the process into two consecutive fractions of approximately equal volume. An isotopic fractionation of 3.0 per mil was measured, with the isotopically lighter fraction coming through the process first. Similar experiments were carried out with limestone and dolomite columns, resulting in smaller but still detectable fractionations.

These laboratory experiments simulate rather poorly actual geological conditions. Nevertheless, they have shown the possibility of obtaining measurable isotopic fractionations of methane by physical processes, such as effusive flow, diffusion and adsorption, similar to those which may occur in Nature during migration and accumulation of hydrocarbons.

In conclusion, although a two-fold mechanism of origin (bacterial and chemical) of the methane from Italian natural gases cannot be discarded, our findings suggest that isotopic fractionation during migration of the gas from the source to the trap positions might be so important as to become the dominant feature of the over-all isotopic fractionation measured.

Details of the experimental techniques and results obtained will be published elsewhere<sup>5</sup>.

## GEOMORPHOLOGY

### Permafrost in England during the Last Glacial Period

PERMAFROST has been shown by many authors to have existed in various parts of England during the last glacial period<sup>1,2</sup>. Its full extent and distribution have remained somewhat uncertain but can be deduced from the occurrence of certain fossil ground structures. Ice-wedge polygons, the trough patterns of chalkland<sup>3</sup>, and the largest stone polygons and stripes are generally accepted as requiring permafrost. Less reliable features are involutions, and a deep layer of upturned stones above horizontally-bedded gravels. Preliminary results are reported here from mapping these structures using pit sections and air photographs.

South-west England seems to have been relatively free from permafrost except on high ground. Permafrost structures are much less frequent than in eastern England. For example, in East Anglia and Kent involutions or fossil ice wedges are found in nearly half the sand and gravel pits, and involutions in one in three chalk pits. In Dorset, by contrast, several miles of suitable face were examined in pits in many places on the Tertiary gravels and the Chalk and only one doubtful set of involutions could be found. The only reason why structures should be so rare in Dorset and the south-west generally would seem to be that permafrost was largely absent. Locally in England permafrost structures are rare for other reasons, which, however, have only very limited application to Dorset. In Surrey, for example, many pits on the Chalk are located on the scarp face where periglacial structures, if they ever occurred, would have been destroyed by post-glacial erosion. Furthermore, involutions are apparent in Chalk only when overlying materials are present and cannot be found in bare Chalk country. This does not explain their absence in Dorset, where the Chalk is not markedly less covered by superficial deposits than in other counties. Again, most of the sand pits in Surrey are in the Folkestone Beds which were evidently too dry for structures to develop. The latter is not the case with pits in the Tertiary beds in Dorset. Permafrost seems to have been widely present in Surrey, for where suitable pits occur structures are frequent.

Fig. 1. Distribution of permafrost during the last glacial period

Extensive permafrost probably extended as far west as the Sussex coastal plain, the western Weald and the Oxford district (Fig. 1). Further west, permafrost seems to have been largely absent from chalk and gravels on low ground. Stone stripes and other structures suggest that permafrost extended down to about 900 ft. on Dartmoor. The lower limit of permafrost in east Devon and west Dorset was probably between 400 ft. and 500 ft. There is reason to suppose that some of the few structures which occur in south-western England are old features dating from the early Weichsel or Gipping glaciations.

The Arctic and Subarctic can be divided into zones of continuous, discontinuous and sporadic permafrost which correspond to different mean annual temperatures<sup>3</sup>. Where the permafrost is patchy, its existence depends on the thermal properties of the ground and the direction of slope<sup>4</sup>. Thus, in the Subarctic in the sporadic zone permafrost is found mostly in peaty materials and on a few north-facing slopes.

It is not immediately clear how the British distribution relates to these divisions. The transition from restricted to extensive permafrost is much more abrupt than in the Arctic. However, the sporadic zone is not properly represented on the map because peaty materials of periglacial age have been little preserved. In eastern England continuous permafrost must have existed at least in certain districts to judge from the abundance of structures. In west Norfolk and Suffolk and parts of Kent, permafrost structures underlie an estimated 50 per cent of the land surface. Permafrost was certainly much more extensive than this figure would indicate since the structures show no preference for slopes facing north-east or damp valley bottoms to which permafrost would tend to be restricted if it were discontinuous. Also the structures would only have developed in part of the area occupied by the permafrost. However, in many districts structures are not found frequently enough to show whether the ground was frozen everywhere. The widespread occurrence of asymmetric valleys also fails to decide whether the permafrost was continuous or chiefly restricted to slopes facing north-east, as many other explanations of the asymmetry are possible<sup>5</sup>. The best evidence is provided by fossil ice-wedges. Most in Britain occur in gravels and sand. In Alaska, wedges in the discontinuous zone are ice-filled only in silts. Even these, according to Péwé, are inactive and relics of former cold conditions. Only in the zone of continuous permafrost are wedges forming at the present day, and only in this zone do wedges in gravels and sand contain ice<sup>6</sup>. The critical mean annual temperature necessary for continuous permafrost is widely accepted as  $-6^{\circ}\text{C}$ . The margin of extensive permafrost

in Britain probably corresponds to this isotherm and suggests the relative importance of Atlantic rather than continental climatic influences in the south-west.

## PHYSICS

### Existence of the Schrödinger and Heisenberg Pictures

IN a recent article in *Nature*<sup>1</sup>, a discussion on the foundations of quantum theory was presented by Dirac. He pointed out that the Schrödinger picture (*S*-picture) does not exist for quantized interacting fields such as quantum electrodynamics. Furthermore, the Heisenberg picture (*H*-picture) is assumed to exist with the *H*- and *S*-pictures not unitarily equivalent. We wish to point out here that there is a natural separable Hilbert space on which the *S*- and *H*-pictures both exist and are equivalent.

Dirac's argument was based on the non-existence of the vacuum state in the *S*-picture. He has introduced a simple model (Dirac, P. A. M., seminar at the Institute for Advanced Studies, Princeton, 1965. We would like to thank Prof. Dirac for communicating this model prior to publication, and for stimulating discussion), in which, by the appropriate representation of the creation and annihilation operators, this difficulty becomes apparent<sup>2</sup>. We wish to show in this model how a suitable representation may be chosen for the *S*-picture to exist.

The Hamiltonian of this model is in terms of a set of Fermion creation and annihilation operators  $N_r, \bar{N}_s$  ( $r = 1, 2, \dots, \infty$ ) satisfying the canonical commutation relations (CCR):

$$[N_r, N_s]_+ = [\bar{N}_r, \bar{N}_s]_+ = 0 \\ [N_r, \bar{N}_s]_+ = \delta_{rs}$$

The Hamiltonian  $H$  is:

$$H = \frac{1}{2} \sum_{r,s=1}^{\infty} (A_{rs} N_r N_s - \bar{A}_{rs} \bar{N}_r \bar{N}_s)$$

$$\text{with } A = \begin{pmatrix} 0 & -10 & 0 & \dots \\ -10 & 0 & 0 & \dots \\ 0 & -10 & 0 & \dots \\ \vdots & \vdots & \vdots & \ddots \end{pmatrix}$$

If we assume  $\bar{N}_r(0)|0\rangle = 0$  for all  $r$ , then it follows that  $\|H|0\rangle\| \rightarrow \infty$ . The conclusion is that the *S*-picture may only be good on some larger non-separable Hilbert space. If instead we choose new variables  $N'_i$  and  $\bar{N}'_i$  (which still obey the CCR) of the form:

$$N'_1 = \frac{\bar{N}_1 - N_2}{\sqrt{2}} \quad N'_2 = \frac{\bar{N}_1 + N_2}{\sqrt{2}} \quad \text{etc.}$$

then  $H = N'_1 \bar{N}'_1 - N'_2 \bar{N}'_2 + \dots$ , which is well defined on the Fock space  $\mathcal{H}$  of the particles described by the operators  $N'_i$  and  $\bar{N}'_i$  provided the number of particles is finite. On this separable Hilbert space  $\mathcal{H}$ , the *S*- and *H*-pictures are well defined and unitarily equivalent.

This model is obviously an over-simplification of the world, but we feel it has at least the essential properties of a full theory which are relevant to the existence question.

When we turn to a more realistic theory such as quantum electrodynamics, we are faced with the problem of diagonalizing a much more complicated Hamiltonian. This is done in principle via the asymptotic in and out fields<sup>3</sup> and will result in practice (in perturbation theory) by inserting the solutions of the field equations as power series expansions in terms of the in or out fields. (From the asymptotic condition,  $H$  is the time translation operator for the in and out fields. The only form of  $H$  expressible as a polynomial in either the in or out creation and annihilation operators must then be the usual diagonal expression for the free energy in terms of these operators.) In the presence of bound states, we do not expect these series to converge and the complete diagonalization will involve a self-consistent type of calculation of these bound states. Even in their absence the convergence is unlikely.

The diagonalization process cannot involve a unitary transformation on the field operators. This is evident for the model discussed earlier and is also true for any relativistic theory as follows from Haag's theorem<sup>4</sup>. Indeed, the Heisenberg operators at finite  $t$  and the corresponding Schrödinger operators must belong to a representation of the CCR<sup>5</sup> which does not possess a no-particle state. These 'strange' representations are very complicated and lead to great difficulties in the  $S$ - and  $H$ -pictures. In fact, all numerical successes of quantum field theory have been obtained by using Green's functions equations (GFE)<sup>6</sup>. These GFE avoid finding the strange representations by considering matrix elements of the field operators and not the operators themselves. We do not know yet whether there exist solutions to these GFE<sup>7</sup>; if we could show that they exist then we would have achieved the diagonalization process outside of perturbation theory.

In conclusion, we see no logical inconsistency in the foundation of quantum field theory provided the non-perturbative solutions of the GFE exist.

### Precursor Shocks produced by a Large-yield Chemical Explosion

PRECURSOR shocks are phenomena normally associated with surface burst or low-level nuclear explosions. The precursor moves out along the ground ahead of the primary shock, and usually produces a large amount of airborne dust. The precursor has been explained<sup>1</sup> as an effect of the intense thermal radiation produced by a nuclear explosion.

In July 1964, a 500 ton TNT hemispherical surface burst charge was detonated at Suffield Experimental Station in Alberta, Canada. High-speed photographs of the explosion show that in some radial directions dust clouds moved out ahead of the main shock and had reached a height of 50 ft. before its arrival. The dust clouds were enveloped by a shock wave. At ground-level this precursor eventually became downward facing and produced a reflected shock and a Mach stem. Photography from an aeroplane at 19,000 ft. immediately above the explosion

showed that all the precursors were produced along well-compacted roadways running radially from the charge centre. The precursors occurred in the region 250–750 ft. from the centre of the explosion, corresponding to peak overpressure levels of 150 lb./in.<sup>2</sup>–20 lb./in.<sup>2</sup>. A gauge measuring the total density within the blast wave, by means of a  $\beta$ -radiation absorption technique<sup>2</sup>, showed the dust density to be four times that of the peak air density expected in the blast wave at that position. Targets placed in the regions of the precursors experienced considerably more damage than had been expected. From the evidence of seismometer records it seems probable that the precursors were produced by strong ground waves feeding energy into the air ahead of the air shock in a manner similar to that observed by Boys<sup>3</sup> for supersonic missiles penetrating metal plates and by Benioff, Ewing and Press<sup>4</sup> for earthquakes.

### Does Quantum Mechanics exclude Life?

P. T. LANDSBERG, in a recent paper<sup>1</sup>, reopened a problem discussed earlier by Wigner<sup>2</sup>: the possibility that quantum mechanics might predict and explain the phenomena of life.

More precisely, this problem may be formulated by asking two questions which sum up its essential content. These derive from a recognition that a living organism, together with the environment from which it draws its food, may be considered as a quantum system of very large size, which we may assume to be isolated from any external influence.

Let us start by supposing that such a system contains initially no living organism. What, then, is the probability that it will evolve towards a state in which a living organism is present? This is the problem of the spontaneous generation of life.

Alternatively, let us suppose that our system contains initially one living organism. What, then, is its probability of evolving toward a state in which two such organisms are present? This is the problem of reproduction.

Wigner sought, essentially, to reply to the second of these two questions: he thus assumed reproduction to be a characteristic and definitive property of life. The conclusion he reached, however, on the basis of a statistical treatment, was that quantum mechanics predicts a practically nil probability for the existence of states corresponding to auto-duplication of a part of the system. He therefore suggested that quantum mechanics is not suitable for a complete description of all natural phenomena or that, at the least, it must be modified to include concepts, such as consciousness, which are not necessary for the description of physical phenomena.

Landsberg deliberately avoids giving any precise definition of a living organism, limiting himself to the assumption that the number of dimensions of the region of phase space, corresponding to the presence of  $n$  living organisms in the system, diminishes very rapidly as  $n$  increases. Using less-restrictive statistical assumptions than Wigner, he establishes that spontaneous generation of life and reproduction are not completely ruled out by quantum mechanics, although their probability on average (that is, over a large number of possible initial conditions) remains extremely small. However, favourable initial conditions for self-reproduction can certainly be expected.

I propose to call attention to two facts. First, in accordance with Landsberg, quantum systems which, when placed in a suitable environment, possess the property of reproducing themselves, do exist, and are moreover fairly well known. Secondly, the contentions of Wigner and Landsberg do not in fact justify any statement on the validity of a quantum mechanical description of life.

The first of these statements is easily demonstrated if one considers an atomic nucleus in an environment with a thermal neutron density always different from zero<sup>3</sup>. In such an environment the nucleus enlarges progressively as a result of successive neutron captures and remains stable, so far as the emission of nucleons is concerned, by successive  $\beta$ -disintegrations. At a certain point, however, it reaches the stability limits for nuclear fission and then, following a final neutron capture, it splits into two nuclei of medium atomic weight. Its behaviour is thus wholly analogous to that of a bacterium in a suitable nutrient.

One certainly cannot maintain that this is a rare or contrived quantum system; this example should rather give us grounds for thought whether the capacity to reproduce in a suitable environment is not one common to all matter.

Furthermore, it is clear that an atomic nucleus does not fall, even marginally, within the category of entities which we describe as living. This means that the capacity to reproduce is not wholly peculiar to these entities, and therefore cannot serve as a quality for their definition. This is why Wigner's and Landsberg's contentions have not in fact anything significant to contribute with regard to the applicability of quantum mechanics to a description of life.

The fact that, for each of the functions (reproduction included) which we consider essential for maintaining life, one can find an inorganic model seems then to suggest a rigidly defined set of ideas. This in fact entitles us to suspect that the problem of ensuring this group of functions may have many very different solutions, and that the single solution which we see universally adopted in the world of living organisms, the cell, is after all only one solution, which has effectively displaced all the others, either through historical events, or more probably because it can ensure a much faster reproductive cycle. In this context, it is interesting to note that the period of duplication of an atomic nucleus exposed to a flux of slow neutrons like that produced by cosmic rays in the atmosphere is of the order of  $10^{18}$  years, and in a nuclear reactor this period would be reduced to  $10^5$  years.

Thus it seems, more generally, that a catalogue of functions is not adequate to define what we call a living being: at least a partial description of the structure of the organism seems essential for an effective definition.

There are in addition many facts which confirm the fundamental nature of the concept of structure (by which we mean the nature and arrangement of the parts constituting the system) as regards both definition and maintenance of life. The most striking of these is the effect of ionizing radiations on living organisms. We know that the permanent changes caused by such radiations in the irradiated material consist almost entirely of the breaking of molecular bonds, which may possibly be followed by the reconstruction of other bonds of the same type. What is thus changed is the arrangement of the particles constituting the cell, and it is clear that this change in the order, that is in the structure of the organism, when it involves certain large molecules of fundamental biological importance, causes a change in the functions which these molecules are intended to perform and thus, triggering a sort of relay amplification process, determines the observable macroscopic damage.

Structure is thus seen, in biology, to be an absolutely basic concept, of which functions are nothing other than dynamic aspects.

But when we remember that the structures we are considering are in point of fact molecular, that is, made of

atoms, it is difficult to see why they could not be described by quantum mechanics.

M. AGENO

Physics Laboratory,  
Istituto Superiore di Sanità,  
Rome.

<sup>1</sup> Landsberg, P. T., *Nature*, 203, 928 (1964).

<sup>3</sup> Ageno, M., *Le radiazioni e i loro effetti*, chap. I (Boringhieri, Torino, 1962); Ageno, M., *La fisica al servizio della medicina*, Rapporti dei Laboratori di Fisica dell'Ist. Sup. Sanità, ISS 64/32 (1964).

PROF. AGENO is correct in quoting inorganic examples of self-duplicating states. Living objects can certainly not be defined by this property alone and this was not our intention. Self-reproduction is, however, one of the properties which has to be discussed from the point of view of quantum mechanics in connexion with living objects. Such a discussion seems to be of interest<sup>1</sup>, even though it can only be very speculative (as pointed out in our publications), since a living system is always large by quantum mechanical standards. We were, therefore, interested in dealing with methods of analysing this problem and in developing assumptions which might reasonably be made in this connexion. As our understanding of these questions increases, one may hope that other features of living matter can be introduced into the argument to make it more specific.

Perhaps it is worth while to point also to a concrete error in Prof. Ageno's argument. Neutron multiplication is not a process of extremely small probability according to quantum mechanics, because the state of the neutrons which are emitted is not a highly specialized one. In contrast, if we asked for the probability that a neutron with a definite energy incident on a uranium nucleus should emit two neutrons with the same energy, the probability would turn out to be very small. The essential point which Prof. Ageno disregards is that the living state is a very uncommon state of the matter of which it is composed, that is, that the same matter can be present in many, many other states which are not living.

## RADIATION CHEMISTRY

### Detection in Denmark of the Sinkiang Nuclear Detonation

MEASUREMENTS of fission products in air at ground level are made regularly in Copenhagen using a high-volume air sampler and a 100-channel  $\gamma$ -spectrometer.

A filter exposed during the period October 23–26, 1964, gave the first reliable indication of new fission-products by the appearance of the 1,596-keV line of lanthanum-140. The sample was a compressed filter containing dust from about 150,000 m<sup>3</sup> air. The measurement position of the filter is close to a 3-in sodium iodide (TI) crystal. The concentration of lanthanum-140 was estimated as  $5 \times 10^{-5}$  pc./m<sup>3</sup>. Filters sampled on October 28 and October 30 show concentrations which are approximately 10 and 100 times greater.

To show the presence of lanthanum-140 clearly in the last-mentioned filter  $\gamma$  -  $\gamma$  coincidence measurement with the 1,596-keV line was made and the 815-, 487- and 329-keV lanthanum lines appeared clearly as shown in Fig. 1.

Fig. 1.  $\gamma$ -Coincidences with 1,596-keV line of lanthanum-140

This seems to prove that debris from the Sinkiang explosion reached Copenhagen by transportation in the upper troposphere in less than 10 days.

Later measurements on a rain sample from October 23 finally proved that the transportation time did not exceed 7 days.

## CHEMISTRY

### Chemical Behaviour of Difluorocarbene, and the Dissociation of the Carbon—Carbon Bond in Tetra-fluoroethylene

**Bond strengths.** The heat of formation of  $\text{CF}_2$  has been estimated through electron impact, thermochemical and kinetic studies. The most recent measurements were obtained through a study of the pyrolysis of  $\text{CF}_2\text{HCl}$  at 530°–750° C, which is believed<sup>1-3</sup> to follow the mechanism:

Either by interpolation from known data, or by assuming the heat of formation of  $\text{C}_2\text{F}_4$  (–151.5 kcal/mole (ref. 4)) and combining this with the thermodynamic data for the equilibrium:

it is possible to estimate the heat of formation of  $\text{CF}_2\text{HCl}$  ( $\sim -112$  kcal/mole); an estimate of the Arrhenius factors of the elementary steps can be derived from the kinetic analysis. Combination of the thermochemical and kinetic data yields  $\Delta H_f(\text{CF}_2) \leq -40$  kcal/mole, and hence  $D(\text{F}_2\text{C}-\text{CF}_2) \leq 70$  kcal/mole. Similar conclusions have been reached by Stull<sup>5</sup>, on the basis of a

study of the formation of  $\text{C}_2\text{F}_4$  from carbon and  $\text{CF}_4$  in a furnace<sup>6</sup>. Majer and Patrick<sup>7</sup> have suggested that higher (less negative) values for  $\Delta H_f(\text{CF}_2)$ , which have been reported on the basis of electron impact studies, result from the production of excited fragments in the primary dissociation.

Whatever may be the absolute value of the heat of formation of  $\text{CF}_2$ , there is little doubt that it leads to a very low value for  $D(\text{F}_2\text{C}-\text{CF}_2)$ , probably  $\sim 70$  kcal/mole, and this conclusion is consistent with other evidence to be presented. By contrast the heat of formation of  $\text{CH}_2$ , although not known with absolute certainty<sup>8</sup>, leads to  $D(\text{H}_2\text{C}-\text{CH}_2) \sim 150$  kcal/mole. However, the C—C bond stretching frequency in  $\text{C}_2\text{H}_4$  is  $\sim 250$   $\text{cm}^{-1}$  lower than in  $\text{C}_2\text{F}_4$  (refs. 9 and 10) and the C—C bond length is  $\sim 0.02$  Å longer. Despite the very low bond dissociation energy in  $\text{C}_2\text{F}_4$ , there is no doubt that, in the region of the potential minimum at least, the carbon atoms remain linked by a double bond.

**Decomposition of fluoromethanes and olefines.** The spectroscopic detection of  $\text{CF}_2$  produced in the flash photolysis of many fluorinated methanes and olefines has been reported<sup>11-13</sup>. Evidence has been obtained, indicating that  $\text{CF}_2$  is produced in a 'molecular' split, in the photolysis of  $\text{CF}_3\text{HBr}$  and  $\text{CF}_3\text{Br}_2$  (and  $\text{CF}_3\text{COOH}$ ); gas chromatographic and mass spectrometric analysis of the volatile products of flash photolysis of  $\text{CF}_2$ :  $\text{CCl}_2$  and  $\text{CF}_2$ :  $\text{CFCl}$  have revealed  $\text{CF}_2$ :  $\text{CF}_2$  and  $\text{CCl}_2$ :  $\text{CCl}_2$ , and  $\text{CF}_2$ :  $\text{CF}_2$  and  $\text{CFCl}$ :  $\text{CFCl}$  respectively<sup>14</sup>. The ready production of  $\text{CF}_2$  from these olefines, and from  $\text{C}_2\text{F}_4$ , with light in the quartz ultra-violet, again emphasizes the ease of dissociation at the C—C bond in these molecules. The products of the Hg ( $6^3P_1$ ) photosensitized decomposition of  $\text{C}_2\text{F}_4$  have been interpreted in terms of a primary dissociation at the C—C bond<sup>15</sup>; this places  $D(\text{F}_2\text{C}-\text{CF}_2) < 112$  kcal/mole.

The ultra-violet absorption spectrum of  $\text{CF}_2$  that is observed after flash photolysis is that of its ground state, which is a singlet,  $^1A_1$ . Its decay is slow and the absorption persists for  $> 20$  msec (ref. 12). Evidently,  $\text{CF}_2$  ( $^1A_1$ ) does not rapidly dimerize in the gas phase at room temperature. If  $\text{CF}_2$  is produced from any of the molecules mentioned here, in an atmosphere of oxygen rather than nitrogen, its yield and decay are not sensibly altered; any homogeneous reaction of  $\text{CF}_2$  in its ground electronic state with molecular oxygen cannot be detected at room temperature. Fielding and Pritchard could find no evidence for reaction between  $\text{CF}_2$  and  $\text{O}_2$ ,  $\text{H}_2$ ,  $\text{CO}$ ,  $\text{C}_2\text{H}_4$  or  $\text{C}_2\text{H}_6$  at 250° C (ref. 16). Kinetic data relating to reactions of  $\text{CF}_2$  in the gas phase have been obtained, however, at 530°–750° C. It was found that the pyrolysis of  $\text{CF}_2\text{HCl}$  is inhibited by addition of  $\text{HCl}$  or  $\text{HBr}$ , and that in the latter case  $\text{CF}_2\text{HBr}$  is a product<sup>2,3</sup>. The activation energies for the reactions:

and:

were estimated to be  $\sim 6$  kcal/mole, though in the latter case the uncertainty in the estimate was greater than the estimate itself. However, it cannot be assumed that the dimerization of  $\text{CF}_2$  requires no energy of activation, in view of the very slow decay of  $\text{CF}_2$  after its production in flash photolysis. Of particular note are the Arrhenius factors for the dissociation of  $\text{C}_2\text{F}_4$ , which were found to be  $10^{16.7} \text{ sec}^{-1}$  and 70 kcal/mole.

The slow decay of  $\text{CF}_2$  ( $^1A_1$ ), produced from  $\text{C}_2\text{F}_4$ , indicates that the initial approach of two  $\text{CF}_2$  molecules in their ground singlet states is repulsive. Let us suppose, then, that near the minimum of its ground electronic state  $\text{C}_2\text{F}_4$  is 'attempting' to dissociate into two  $\text{CF}_2$  molecules in their lowest triplet state,  $^3B_1$  (assumed to be non-linear by analogy with  $\text{SO}_2(^3B_1)$ , with which it is iso-electronic<sup>17</sup>). The initial approach of two triplet species would be

Fig. 1. Potential energy curves for  $C_2F_4$  (a) and  $C_2H_4$  (b)

attractive, and would be represented by a descending potential curve; it would cross the repulsive curve correlating with two normal  $CF_2(^1A_1)$  molecules, since these will lie at a lower energy. The nett result is represented in Fig. 1a, where the potential energies are plotted as a function of the C—C separation (assuming that the remaining bond lengths and valence angles are 'frozen'). In  $C_2H_4$ , the products of dissociation at the C—C bond would be  $CH_2$ , which has a triplet ground state,  $^3\Sigma_g^-$  (ref. 18). As in the case of  $CF_2(^3B_1)$ , these would approach each other along an attractive curve, but one which now cannot cross the curve correlating with  $2CH_2(^1A_1)$ , since this lies at higher energies (see Fig. 1b).

Some consequences of this interpretation can be listed: (i) The dissociation energy of the C—C bond in  $C_2F_4$  will be reduced by an energy approximating to twice the energy of  $CF_2(^3B_1)$  above its ground state. The depth of the perturbed curve representing the ground electronic state of  $C_2F_4$  is  $\sim 70$  kcal/mole below its dissociation limit. Assuming that dissociation to two triplet carbenes requires  $\sim 160$  kcal/mole, as in  $C_2H_4$ ,  $CF_2(^3B_1)$  is estimated to lie  $\sim 45$  kcal/mole above  $CF_2(^1A_1)$ ; (ii) the association of two singlet  $CF_2$  molecules will require an activation energy the magnitude of which will depend on the height of the 'cross-over' point; (iii) the first excited singlet state of  $C_2F_4$  will possess a relatively shallow minimum and a considerably increased equilibrium C—C distance. The longest wave-length ultra-violet absorption of  $C_2F_4$  should be continuous on the basis of the Franck-Condon principle, and lead to dissociation at the C—C bond. In the event of predissociation the primary products would be singlet  $CF_2$  molecules. The ultra-violet absorption is indeed continuous at wave-lengths around  $2000 \text{ \AA}$  (ref. 19), and it is this transition which is excited in the flash photolysis of  $C_2F_4$ ; (iv) the C—C stretching frequency in the ground state of  $C_2F_4$  should show strong anharmonicity—this might be detected if high overtones could be observed in its infra-red spectrum. There is no conflict between the low dissociation energy of the C—C bond and its high stretching frequency, since the former relates to the behaviour of  $C_2F_4$  at its dissociation limit, and the latter to its behaviour around the minimum, where it is unaffected by the perturbation occurring at higher energies; (v) the Arrhenius factors for the dissociation of  $C_2F_4$  should reflect the perturbation of the ground state curve. The high-frequency factor ( $10^{16.7} \text{ sec}^{-1}$ ) is consistent with completely free rotation in the transition state (at the top of the maximum in the ground state curve), as has been proposed in the dissociation of  $N_2O_4$ .

It is of interest to extend the interpretation to the mixed ethylene  $CF_2:CH_2$ . In this case, one may expect the dissociation energy to be reduced by only half the amount in  $C_2F_4$ , since  $CH_2$  has a triplet ground state. The difference between the dissociation energy of  $CF_2:CH_2$  and

$CF_2:CF_2$  should be the energy of  $CF_2(^3B_1)$  above its ground state. The heat of formation of  $CF_2:CH_2$  is  $-77.5$  kcal/mole<sup>4</sup>, and taking  $\Delta H_f(CF_2) \sim -40$  kcal/mole and  $\Delta H_f(CH_2) \sim 86$  kcal/mole,  $D(H_2C-CF_2) \sim 123$  kcal/mole. Subtracting  $D(F_2C-CF_2)$  from this leaves  $\sim 53$  kcal/mole, which is reasonably close to the estimate of  $\sim 45$  kcal/mole for the excitation energy of  $CF_2(^3B_1)$ , considering the approximate values for the numerical data. Flash photolysis of  $CH_2:CF_2$ , using light of wave-length greater than  $1700 \text{ \AA}$ , does indeed result in the transient appearance of  $CF_2$  ultra-violet absorption bands, though with an intensity greatly reduced in comparison with  $C_2F_4$ , consistent with the greater energy required for dissociation.

I thank Prof. A. D. Walsh for his advice.

## Nuclear Magnetic Resonance Standards for Aqueous Solutions

FOR the nuclear magnetic resonance investigation of interaction in solution, careful consideration must be given to the choice of standard against which changes in chemical shift are to be measured. An external standard is in many ways ideal, but a correction has then to be applied to the observed chemical shift, due to differences in bulk magnetic susceptibilities. The true chemical shift  $\delta$  is given by the equation:

$$\delta = \Delta\nu + g(\chi_{\text{ref}} - \chi_{\text{sol}}) \quad (1)$$

where  $+\Delta\nu$  is the observed upfield shift, in p.p.m., of a line with respect to the reference, and  $\chi_{\text{ref}}$  and  $\chi_{\text{sol}}$  the volume magnetic susceptibilities of the reference and solution being investigated. The value of  $g$  is determined by the shape of the interface of contact between the reference and the solution. Since it is somewhat tedious to measure susceptibilities<sup>2</sup>, many investigators have either ignored any corrections (thereby invalidating the work<sup>3</sup>) or have used internal standards, for which no susceptibility corrections have to be applied.

We used dioxan<sup>4</sup> as an internal standard for an investigation of aqueous resorcinol solutions. It transpired that the effects due to resorcinol-dioxan interactions are much greater than the effect due to resorcinol-water interactions. This highlights the danger of using an internal standard. To avoid interactions involving the reference compound, external standards must be used. The required  $\chi$  values can be determined by the nuclear magnetic resonance method using a stationary pair of coaxial cylindrical tubes<sup>5</sup>. In our hands these tubes proved difficult to make and those that were made had such a large geometrical asymmetry as to give results even less accurate than those previously reported<sup>2</sup>.

Fig. 1. Sample tube assembly

With cylindrical interfaces,  $g_{\text{cyl}}$  is theoretically  $2\pi/3$ . However, for a spherical contact interface,  $g_{\text{sph}}$  is theoretically zero, in which case susceptibility values would not be required. We made spheres about 3.5 mm in diameter, blown on the end of 1.65 mm (outer diam.) glass tubing. These tubes (Fig. 1) were then mounted, by using PTFE tape, inside tubing (3.5 mm outer diam.) placed inside standard Perkin-Elmer 4.6 mm soda-glass nuclear magnetic resonance tubes containing the system to be examined. The centre of the sphere was arranged to be 2.5 cm above the bottom of the nuclear magnetic resonance tube which, on the Perkin-Elmer R-10 used, brought it in the centre of the detecting coil. Measurements were made on various dioxan-water mixtures using this arrangement. The results were compared with those obtained with the same solutions, but using a cylindrical external standard. The susceptibilities required to correct the latter results were taken from published data<sup>6</sup>.

Table 1. CHEMICAL SHIFTS IN DIOXAN-WATER MIXTURES

5.0	1.587	1.752	-0.106	-0.222	1.587	+0.007	0.215
10.0	1.188	1.387	-0.100	-0.209	1.178	+0.010	0.199
15.0	0.942	1.140	-0.093	-0.195	0.945	-0.003	0.198
20.0	0.780	0.943	-0.086	-0.180	0.763	+0.017	0.163
35.0	0.520	0.648	-0.065	-0.136	0.512	+0.008	0.128
50.0	0.291	0.383	-0.047	-0.098	0.285	+0.006	0.092
65.0	0.170	0.222	-0.031	-0.065	0.157	+0.013	0.052
80.0	0.068	0.100	-0.017	-0.036	0.064	+0.004	0.032
90.0	0.030	0.042	-0.008	-0.017	0.025	+0.005	0.012

The recorded shifts are of the water line with reference to (external) water, in p.p.m. at 60 Mc/s.

The two sets of results (Table 1) are, within our experimental errors, identical. This can also be seen as follows. Combining two equations of the form of (1) leads to equation (2):

$$\Delta\nu_{\text{cyl}} - \Delta\nu_{\text{sph}} = (g_{\text{cyl}} - g_{\text{sph}})(\chi_{\text{sol}} - \chi_{\text{ref}}) \quad (2)$$

A plot of  $\Delta\nu_{\text{cyl}} - \Delta\nu_{\text{sph}}$  against  $\chi_{\text{ref}} - \chi_{\text{sol}}$  should therefore give a straight line passing through zero, of slope  $g_{\text{cyl}} - g_{\text{sph}}$ , or  $\frac{2}{3}\pi - 0 = 2.095$ .

The data in the table lead to such a line with a least means square slope of 2.080 (standard deviation 0.041). This either means that  $g_{\text{cyl}}$  is less than  $2\pi/3$  or that  $g_{\text{sph}}$  is 0.015. At the worst, for a susceptibility difference of  $0.3 \times 10^{-6}$  (and by careful choice of reference compound a much smaller value will ordinarily be possible), then the error introduced by assuming  $g_{\text{sph}} = 0$  should be less than 0.0045 p.p.m., 0.5 c/s at 60 Mc/s.

Although some loss of resolution occurs the present results demonstrate the usefulness of a spherically shaped external standard<sup>7</sup>.

Finally, it should be noted that, at the low-water concentration region, the data presented here differs from that previously given for dioxan-water mixtures<sup>6</sup>. This is due to an error in the concentrations in the earlier work<sup>8</sup>.

## Unpaired Electrons in Ultra-violet-irradiated Keratin

RECENT work on the electron spin resonance signals observed in ultra-violet-irradiated proteins<sup>1</sup> has stimulated interest in the theory that proteins may exhibit conduction band properties. In experiments with ultra-violet irradiated proteins and amino-acids carried out in this laboratory, results have been obtained which in a particular instance may support such a theory.

Several amino-acids and the proteins gelatin, insulin, casein, silk fibroin, egg albumin and unpigmented keratin were evacuated and sealed in quartz sample tubes. The samples were then irradiated by narrow wave-length bands of monochromated ultra-violet radiation in the spectral range 250–600 mμ to doses of the order of  $10^{20}$  quanta. An X-band electron spin resonance spectrometer, using 110-kc/s magnetic field modulation, was used to detect any free radicals present in the samples before and after irradiation. The keratin samples were the only samples to exhibit electron spin resonance signals before the irradiation treatments. Such a signal (Fig. 1) has previously been observed with wool<sup>2</sup>, and in the specimens examined here the magnitude of the electron spin resonance signal indicated a free radical concentration of the order of  $10^{13}$  per g.

The results observed following the irradiations were generally in accordance with the energy absorptions of the samples. For example, radiation bands of wave-length less than 325 mμ, which are absorbed by chromophoric groups known to be present in proteins<sup>3</sup>, produced significant electron spin resonance spectra, indicating that free radicals, stable in vacuum, were formed as a result of the irradiation-induced photolytic reactions<sup>4,5</sup>. Radiations of wave-lengths greater than 325 mμ, which are not absorbed by any known protein chromophores, produced no significant electron spin resonance signal in any of the proteins with the exception of the keratin samples.

In the case of the unpigmented keratins (various types of wool and rhinoceros horn) a strong electron spin resonance signal (approximately  $10^{14}$  spins/g) was observed

Fig. 1. Electron spin resonance spectrum of keratin before irradiation

Fig. 2. Electron spin resonance spectrum of keratin after irradiation at 360-400 mμ

Fig. 3. Electron spin resonance spectrum of keratin irradiated at 300-325 mμ. —, Original spectrum; ---, 5 min aeration; ..., 1 h aeration

After irradiation at the wave-length intervals of 325-360, 360-400 and 400-600 mμ. This electron spin resonance signal (Fig. 2) was quite different from that produced in keratin by irradiation at shorter wave-lengths (Fig. 3). Furthermore, the electron spin resonance signal was stable in air and could be produced in the presence of air at a rate comparable with its production in vacuum, whereas the electron spin resonance signal produced by radiation at shorter wave-lengths decreased on the admittance of air to the sample (Fig. 3) due to radical decay. These results clearly indicate that the radicals produced by long ultra-violet and visible radiation are quite different from those produced by radiation of wave-lengths of less than 325 mμ. The similarity between spectra of the keratin samples before irradiation, and after irradiation at longer wave-lengths, suggests that the signal observed before irradiation (Fig. 1) may have been the result of exposure to radiation during growth.

The electron spin resonance signals observed following the exposure of keratin to long ultra-violet and visible radiation is very similar, in stability to oxygen, line width, line shape and  $G$  value, to the electron spin resonance spectra of melanin and certain carbon samples where unpaired electrons are considered to be highly mobile in some form of conduction band<sup>1</sup>. This suggests that the electron spin resonance spectrum of irradiated keratin is generated by the excitation of electrons into a conduction band in which they are highly mobile. This conduction band may be associated either with the protein molecule or with some non-protein impurity present in the keratin. If the former is the case, then the structure of the  $\alpha$ -keratin must play an important part, since no comparable electron spin resonance signal was observed for silk fibroin—a protein the molecular structure of which could lend itself to conduction band properties to the same extent as  $\alpha$ -keratin<sup>6,7</sup>. Alternatively, the conduction band could be associated with some non-protein impurity in the form of either melanin pigmentation (in minute quantities since the keratin samples appeared to be unpigmented) or some unpigmented precursor to melanin. The fact that the only protein investigated which exhibited the conduc-

tion band properties, namely keratin, was also the only protein of this group likely to be associated with melanin pigmentation leads us to believe that the second alternative is the more likely explanation.

### Phase Transformation of Thin Caesium Chloride Layers

In connexion with investigations on the structural properties of thin ionic crystal layers, the phase transformation of caesium chloride was examined by means of electron diffraction. The specimens (Merck p.a.) were prepared in a Balzers 350-G vacuum device at  $2 \times 10^{-5}$  torr by evaporation from a molybdenum boat, and then investigated in a hot-stage electron diffraction specimen holder of a Hitachi HU-10A electron microscope operated at 75 kV. In order to prevent sublimation during heating the caesium chloride crystal layers were coated, in the vacuum evaporator, with a thin carbon film. The contrast of the diffraction patterns was only slightly affected by this procedure. The layer thicknesses expected<sup>1</sup> were 20 Å and 300 Å, respectively. The  $L\lambda$  values ( $L$  is the tube length and  $\lambda$  is the electron wave-length) were determined with a thallium chloride standard<sup>2</sup>.

According to the experimental results, the (200), (220) and (420) rings of the  $\beta$ -phase appeared at 703° K. However, the layer structure remained mixed at this temperature since a major part of the rings of the  $\alpha$ -phase was also observed. Above 723° K only the  $\beta$ -phase remained ((200), (220), (311) and (420) rings). The temperature values may not be exact, as allowance should be made for the heating effect of the electron beam.

Fig. 1 shows a typical example for the  $\alpha$ -phase at room temperature and the  $\beta$ -phase above 723° K.

Once the  $\beta$ -phase developed it remained very stable and could be brought down to room temperature. The first rings of the  $\alpha$ -phase ((211), (221), (310) and (400)) only appeared after several hours at room temperature (Fig. 2). The  $\beta$ -phase of the layers with an expected thickness of

Fig. 1

Fig. 2

20 Å proved to be quite stable, whereas thicker layers (300 Å), when cooled to room temperature, readily transformed into the  $\alpha$ -phase.

The lattice constant as determined from the (211) ring of the  $\alpha$ -phase at room temperature was  $4.09 \pm 0.05$  Å, and for the  $\beta$ -phase, as determined by the intensive (200) ring at 723° K,  $7.00 \pm 0.06$  Å. The value of the lattice constant showed an expansion with the temperature.

We thank Prof. S. Lengyel for advice and Mrs. L. Fülöp for helping us to carry out the experiments.

### Crystal Structure of Monomethyltriethyl Titanate

In solution most of the titanium orthoesters have been shown to be associated into trimers<sup>1-3</sup>, and a structure has been proposed for the trimeric aggregate<sup>1</sup>. There has been considerable interest in the structure of this aggregate<sup>3-5</sup>. In 1963 Ibers<sup>6</sup> reported a preliminary crystal structure of tetraethyl titanate showing this to be tetrameric, not trimeric, in the solid state. We have now determined the main features of monomethyltriethyl titanate and have found it also to be tetrameric in the solid state. However, large thermal motion and the limited amount of data for the large number of parameters in the cell have prevented our locating all the carbon atoms or obtaining precise bond distances and angles. Low-temperature data are now being collected to complete the structure determination.

Intensity data were collected by the multiple film technique using a Supper Weissenberg camera. 751 non-equivalent reflexions were observed on levels zero through six. Diffraction data showed that the crystal belonged to the triclinic system and gave the following cell parameters:  $a = 12.13$  Å,  $b = 12.14$  Å,  $c = 16.93$  Å,  $\alpha = 76^\circ 56'$ ,  $\beta = 77^\circ 2'$ , and  $\gamma = 74^\circ 15'$ . With eight monomer units/unit cell, the calculated density is 1.236 g/c.c.; the measured density is 1.244 g/c.c.

From a three-dimensional Patterson map the eight titanium atoms were located, showing the molecules to be arranged in tetramer units. The titanium atoms in each tetramer form a planar diamond-shaped pattern, both tetramers lying parallel to the  $ab$  crystal plane, and displaced from each other one-half a unit cell edge along the  $c$  axis, with corresponding titanium atoms in each unit having the same  $x$  and  $y$  co-ordinates. In the early stages of the structure determination it was assumed that the crystal was centrosymmetric. With the titanium atoms thus located, an electron density map was calculated. Due to this arrangement of the titanium atoms, twice the number of expected oxygen peaks appeared on the map since at this point there was nothing to distinguish between the two titanium tetramers. With the restriction

that the co-ordination number of titanium be six, only one chemically reasonable structure could be found, and this was essentially the same as that reported by Ibers<sup>6</sup> for the tetraethyl titanate.

Once the oxygen positions were included the ambiguity between the two tetramer units was removed, and the subsequent electron density maps were normal. Several carbon atoms were located from electron density maps, from minimum function maps, and from difference maps. Fig. 1 indicates the general structure of the tetramer unit.

Fig. 1. Structure of  $\text{Ti}(\text{OCH}_3)(\text{OC}_2\text{H}_5)_3$  tetramer. Large circles are titanium atoms; small circles are oxygen atoms; carbons not shown

With only titanium atoms located, the usual discrepancy index was 0.585; when all oxygens were included, the index dropped to 0.32. Refinement was continued using a block-diagonal matrix least squares programme written by van der Helm<sup>7</sup> and modified by George Svetich<sup>8</sup> for card input for the IBM 1620 computer. With half the carbon atoms included, refinement stopped at a discrepancy index of 0.23. Up to this point it had been assumed that the crystal belonged to the centric space group  $P\bar{1}$ .

Consideration of the possible structure of the crystal suggested that even if the titanium and oxygen atoms in the tetramer unit were related by a centre of symmetry, there was no reason to expect the structure to be centric with respect to the carbon atoms. With 46 carbon atoms included a cycle of a full matrix least squares was run on the IBM 709 at the University of Washington. The discrepancy index dropped to 0.136, assuming the crystal to belong to the space group  $P1$ . Many bond distances and angles appeared to be improbable, and temperature factors of some of the carbons ranged from 12 to 19. The remaining ten carbon atoms could not be found. Undoubtedly this inability to complete the structure determination is due to the limited amount of data. With 86 atoms, each with isotropic temperature factors, the number of parameters to be adjusted is 344. The number of observed reflexions used was 746, giving an over-determination of only 2.17.

Although the complete structure was not determined, the following essential features were found. (1) The unit cell is occupied by two tetramer units which are parallel to the  $ab$  plane. The second tetramer may be generated, approximately, from the first by 180° rotation of the first about an axis perpendicular to the  $ab$  plane and passing through the centre of the tetramer, followed by translation one-half the unit cell length along the  $c$  axis. (2) Each tetramer unit is very nearly centrosymmetric, at least with respect to the titanium and oxygen atoms. (3) The oxygen atoms lie approximately in planes above and below the plane of the titanium atoms. (4) There are three types of oxygen atoms: (a) those associated with only one titanium atom; (b) those associated with two titanium atoms; and (c) those associated with three titanium atoms. (5) Titanium-oxygen bond distances vary from about

1.6 Å to 2.4 Å. Generally, the greater the number of titanium atoms associated with an oxygen atom, the longer are the bonds. (6) The distances between adjacent titanium atoms vary from 3.3 Å to 3.5 Å. (7) In each case the co-ordination number of titanium is six. Fig. 1 shows the structure of the tetramer unit without the carbons.

### Use of 2,4-Dinitrophenylhydrazine for the Estimation of Micro Amounts of Carbonyls

THE use of 2,4-dinitrophenyl hydrazine (2,4-DNP hydrazine) in acid solution as a reagent for the estimation of methyl ketones and other carbonyls is common despite the fact that the reaction is apparently non-quantitative<sup>1-3</sup>. Between 20 and 90 per cent recoveries of methyl ketones from aqueous solution have been reported<sup>4,5</sup>. Wong, Patton and Forss<sup>4</sup> attributed the low recovery of 2-pentanone (25 per cent) from whole milk by steam distillation under reduced pressure to the non-completion of the reaction with the reagent. Haverkamp Begemann and de Jong<sup>5</sup> concluded that the method of shaking had a marked influence on the yield of 2,4-DNP hydrazone, and by use of a 'Celite'/2,4-DNP hydrazine column to ensure more intimate contact between the reagent and the carbonyl compound they achieved practically complete conversion into the 2,4-DNP hydrazone.

In a recent investigation in this laboratory of the oxidation of fatty acids to methyl ketones by the fungus *Penicillium roqueforti* a rapid and accurate method of estimating the methyl ketones formed was required. An investigation was therefore made of the causes of the low recoveries of methyl ketones as their 2,4-DNP hydrazones, in an attempt to devise a method which would be accurate and also less time-consuming than the column method of Haverkamp Begemann and de Jong<sup>5</sup>.

Jencks<sup>6</sup> suggested that in strongly acid solution there is an initial reversible addition of phenylhydrazine, and presumably therefore of 2,4-DNP hydrazine, to a carbonyl compound to give an intermediate that undergoes acid-catalysed dehydration:

In acid solution the concentration of free phenylhydrazine is so low that the first step is considered to be rate-controlling.

In preliminary experiments, 2,4-DNP hydrazones of methyl ketones dissolved in 2 N HCl were found to dissociate slowly in an open vessel, the foregoing equilibrium presumably moving to the left with time as a result of evaporation of the volatile ketones. The extreme insolubility of the 2,4-DNP hydrazones of methyl ketones above

% decrease	80	79	37	21	8

1 ml. standard aldehyde solution added to 2 ml. 2,4-DNP hydrazine reagent.

C<sub>6</sub> in 2 N HCl, however, prevented a detailed investigation. As an alternative approach the 2,4-DNP hydrazones were prepared *in situ* by adding 1 ml. aliquots of standard ketone solutions (0.75 μmoles/ml.) to 2 ml. 2,4-DNP hydrazine reagent (2 g/l. 2 N HCl) both in a series of 50-ml. beakers and in stoppered 25-ml. test-tubes. At intervals the 2,4-DNP hydrazones were extracted with 20 ml. hexane from one of each of the vessels as detailed below. The yield of 2,4-DNP hydrazones from the beakers slowly decreased with time, with the greatest decrease in the 2,4-DNP hydrazones of the lower methyl ketones (Table 1). When the stoppered test-tubes were used the recovery of the ketones as their 2,4-DNP hydrazones was virtually quantitative.

Similar investigations showed that n-saturated aldehydes formed more stable 2,4-DNP hydrazones than the corresponding methyl ketones. This was presumably a reflexion of their greater relative additive power with 2,4-DNP hydrazine and, by analogy with the equilibrium constants for the formation of the bisulphite addition compounds from a number of aldehydes and ketones<sup>7</sup>, may be attributed to both steric and electronic factors. The 2,4-DNP hydrazones of the most volatile aldehydes (C<sub>2</sub>-C<sub>4</sub>) were the least stable and those of the higher aldehydes (C<sub>7</sub> and C<sub>10</sub>) the most stable (Table 2). As with the methyl ketones the greatest loss of aldehyde in the open beakers occurred in the first 15 min.

Since it was probable that the low recoveries obtained by other investigators were a result of the volatility of the carbonyls in aqueous solution, a method of estimation was developed which reduced the number of operations leading to the final determination of the 2,4-DNP hydrazones in a spectrophotometer. 1 ml. of the aqueous ketone solution was allowed to stand for 30 min with 2 ml. of 2,4-DNP hydrazine in a stoppered test-tube, 20 ml. of carbonyl-free hexane, prepared according to the method of Schwartz and Parks<sup>8</sup>, were added and the mixture was vigorously shaken. The aqueous and hexane layers were allowed to settle, the upper hexane layer, which contained the 2,4-DNP hydrazone, was poured directly into a Beckman cell and its absorption read at 345 mμ in a Beckman DU spectrophotometer. A 'blank', prepared by shaking 2 ml. of 2,4-DNP hydrazine reagent with 1 ml. of water and 20 ml. carbonyl-free hexane, corrected for the slight solubility of the reagent in the hexane. The concentration of the methyl ketones could then be obtained directly from standard curves relating absorption at 345 mμ to the concentration of 2,4-DNP hydrazone. The recovery of up to 5.0 μmoles/ml. of the higher (C<sub>6</sub>-C<sub>11</sub>) ketones as their 2,4-DNP hydrazones by this method was quantitative. The 2,4-DNP hydrazones of the C<sub>3</sub>-C<sub>5</sub> methyl ketones are less soluble in hexane than those of

the higher methyl ketones, but 3  $\mu$ moles were extracted quantitatively by 20 ml. hexane.

It seems possible that part of the variation and low yields obtained by some investigators<sup>4,9</sup> when distilling carbonyls directly into 2,4-DNP hydrazine reagent results from both the volatility of the carbonyls and the instability of the carbonyl-reagent adduct. When 1 ml. of standard carbonyl solution was added to 2 ml. of reagent and a vacuum applied by means of a water pump, a similar pattern of recovery with time resulted as with the open beakers, despite the much lower surface-to-volume ratio in the vacuum trials.

This investigation has shown that although the 2,4-DNP hydrazones of volatile carbonyls in acid solution are not stable in open systems, under closed conditions the reaction of 2,4-DNP hydrazine with carbonyls up to C<sub>11</sub> is quantitative and rapid, shaking not being necessary. Contrary to another report<sup>10</sup> the reaction was found to be complete within 30 min.

### Thermal Decomposition of Irradiated Calcium Azide

THE investigations of Andreev<sup>1</sup> and Marke<sup>2</sup> of the isothermal decomposition of calcium azide showed that the decomposition comprised a marked induction period followed by a period of acceleration where the exponential relationship:

$$\log p = k_1 t + c_1 \quad (1)$$

fitted to a limited extent. The decay period of the decomposition was considered to follow the unimolecular decay law:

$$\log (p_f - p) = k_2 t + c_2 \quad (2)$$

where  $p_f$  is the final pressure.

The degree of reproducibility of the pressure-time plots for whole and ground crystals was poor. Marke found no pronounced change in  $k_1$  on grinding the crystals and determined approximate activation energies of 18 kcal mole<sup>-1</sup> and 19 kcal mole<sup>-1</sup> for the acceleratory and decay periods, respectively. Andreev's value for the acceleratory period was 22.8 kcal mole<sup>-1</sup>.

In contradiction, Garner and Reeves<sup>3</sup> concluded that the acceleratory period followed the power law:

$$p^{1/3} = k_3 t + c_3 \quad (3)$$

Reproducibility of results again was not good. A four-fold increase in  $k_3$  was found on grinding the crystals, and exposure to ultra-violet light in air accelerated the reaction and shortened the induction period. Equation (3) still fitted the pressure-time plots for irradiated material. The average activation energy for the decomposition of unirradiated salt during the acceleratory period was 18.2 kcal mole<sup>-1</sup>. It was of interest to determine whether: (1) the reproducibility of the decomposition could be improved; (2) reliable activation energies could be obtained; (3) the uncertainty relating to the correct kinetic expressions for the decomposition could be

resolved. In addition, pre-irradiation with  $\gamma$ - and X-rays could be expected to accelerate the decomposition as was found with barium<sup>4</sup> and strontium<sup>5</sup> azides.

Fig. 1 shows the pressure-time plots and the corresponding mathematical analysis for the decomposition of unirradiated, ground, calcium azide prepared by the method of Marke using materials of high purity. The plots for ground and whole crystal agglomerates were practically identical at a given temperature. Reproducibility of results was excellent. The acceleratory period conformed to the power expression, equation (3), and the decay reaction to the contracting sphere formula:

$$[1 - (1 - p/p_f)^{1/3}] = k_4 t + c_4 \quad (4)$$

The plots of  $\log k_3$  and  $\log k_4$  versus  $1/T(^{\circ}\text{K})$  were good straight lines and the activation energies (ground material) for the acceleratory and decay periods were 27.1 and 18.8 kcal mole<sup>-1</sup>, respectively. The activation energy for processes occurring during the induction periods, as determined from the plot of  $\log$  (induction period) versus  $1/T(^{\circ}\text{K})$ , was 18.2 kcal mole<sup>-1</sup>.

Fig. 1. Curve A, pressure-time plot for decomposition of unirradiated calcium azide at 115°C; line B,  $p^{1/3}$  versus  $t$ ; line C,  $[1 - (1 - p/p_f)^{1/3}]$  versus  $t$ .

Irradiation of calcium azide in air is unsatisfactory since any photolysis or radiolysis on the surfaces of the crystals to give nuclei of, say, calcium or calcium nitride will be accompanied by oxidation processes. Consequently, all irradiation and subsequent handling were done in an atmosphere of nitrogen. The effects of pre-irradiation by X-rays (copper target, unfiltered beam 40 kV and 20 m.amp), ultra-violet light, and  $\gamma$ -rays ( $\sim 1$  MeV) on the subsequent thermal decomposition are shown in Fig. 2. Equations (3) and (4) fitted the pressure-time plots for the decomposition of X-ray, ultra-violet and  $\gamma$ -ray irradiated calcium azide. Activation energies for the decomposition of  $\gamma$ -ray irradiated (8 Mrads) azide were 19.8, 28.1 and 22.5 kcal mole<sup>-1</sup> for the induction, acceleratory and decay periods, respectively.

Fig. 2. Pressure-time plots showing the effect of pre-irradiation on thermal decomposition of calcium azide at 100°C. Curve A, unirradiated (induction period ends at 200 min); curve B, pre-irradiated by ultra-violet light for 15 h; curves C and D, pre-irradiated by  $\gamma$ -rays with doses of 0.25 Mrad and 8 Mrads respectively; curve E, pre-irradiated by X-rays for 8 h.

Electrical conductivity measurements of irradiated and unirradiated azide are being made and these and further observations and conclusions arising from this study will be published elsewhere.

## BIOCHEMISTRY

### Conformational Investigations of Histones

WE have carried out some investigations into the conformations of whole histones and histone fractions under various conditions. The experiments on repression of DNA-dependent RNA synthesis with histones<sup>1,2</sup>, native nucleohistone<sup>3</sup>, and DNA combined with histone fractions<sup>4-10</sup> have led to a renewed interest in the hypothesis of Stedman and Stedman<sup>11</sup> that one of the functions of histones is the regulation of genetic activity. However, the results of the various experiments on the repression of DNA-dependent RNA synthesis are not in agreement with one another, and the inhibitory capacities of the various histone fractions appear to depend on the method of preparation of the recombined nucleohistone, particularly the relative proportions of histone and DNA used for recombination, and perhaps even on the preparation of the histone fractions themselves. These apparently conflicting results indicate the need to investigate the conformations of the histone fractions, prepared by different methods, under conditions used to reconstitute the nucleohistones.

The histones and histone fractions examined were prepared from calf thymus tissue at two laboratories: in the Chester Beatty Research Institute using methods described by Phillips and Johns<sup>12</sup> and Johns<sup>13</sup>, and at the Department of Chemistry, Stanford University, California, according to the procedures given by Satake, Rasmussen and Luck<sup>14</sup>, and also by Murray<sup>15</sup>. In all cases the final product was a histone in the form of a dry powder.

The optical rotations of whole histones and histone fractions have been measured at nine wave-lengths in the range 5780–2967 Å with the spectropolarimeter designed by Malcolm and Elliott<sup>16</sup>, and the rotations were analysed according to Moffitt's equation<sup>17</sup>. The value used for  $\lambda_0$  was 2120 Å since this was found to give the best linear plot of the results in the foregoing wave-length range. In addition to the optical rotatory dispersion measurements, infra-red spectra of insoluble fractions and insoluble portions of fractions were recorded on a Grubb Parsons 'Spectromaster'. Some samples prepared according to the procedure described by Satake, Rasmussen and Luck<sup>14</sup>, which involved freeze-drying, were incompletely soluble in the various solvents. Their infra-red spectra, particularly those of the insoluble residues, showed, in addition to the bands characteristic of helical and random forms, bands at 1,686 cm<sup>-1</sup> ( $\nu$ ), about 1,630 cm<sup>-1</sup> ( $\nu$ ) and about

1,525 cm<sup>-1</sup> ( $\nu$ ). These bands indicate the presence of large amounts of the extended antiparallel  $\beta$ -conformations in these preparations. Elimination of freeze-drying from the preparative procedure resulted in samples which were completely soluble in the various solvents, and their infra-red spectra showed the absence of  $\beta$ -material. It is essential to avoid freeze-drying of histone fractions if they are to be used for physical investigations.

Table 1 shows the values of  $b_0$  obtained for the different preparations of whole histone and histone fractions in water and in aqueous sodium chloride solutions. Also given are values obtained in 2-chlorethanol, a solvent known to favour formation of helices in proteins. Four preparations of histone fractions prepared at the Chester Beatty Research Institute and two preparations from Stanford University were examined. Histone fractions prepared at the former institute are designated F1, F2a, F2b and F3, while similar, though not necessarily identical, histone fractions from Stanford University are designated Ib, Ila, IIb and (III and IV). Assuming that a  $b_0$  value of -630 represents a fully helical protein, it is seen that in 2-chlorethanol the histone fractions have an approximate helical content of about 46 per cent for fractions F1 and Ib, and 65–70 per cent for F2a, F2b, F3, IIb and (III and IV). However, in aqueous solutions the histone fractions are largely in a random conformation, and in the case of fractions F1 and Ib completely so. The addition of salt to these aqueous solutions causes a small increase in helix content, presumably due to a decrease in the repulsion between like-charged side-chains. Measurements were made in salt solution up to 3 M, though a salt molarity of 1.0 was found to be sufficient to produce this increase in helix content of about 10–20 per cent. The low helix content of the histone fractions in salt solutions contrasts with the estimates of 50–60 per cent<sup>18,19</sup> for the helix content of whole histone in native nucleohistones, though it must be emphasized that these estimates need to be confirmed by other techniques. The results presented here suggest that the histone fractions which have been used in the preparation of reconstituted nucleohistone were mainly in a random conformation; whether or not their interaction with DNA in the reconstitution experiments causes the histones to assume their native conformation remains to be determined.

Another noteworthy feature of the results is that histone fractions F1 and Ib are significantly less helical than the other fractions both in 2-chlorethanol and in salt solutions, and this may be correlated with the high proline content (about 9 per cent) of these fractions. In addition, Johns and Butler<sup>20</sup> have shown that in recombination experiments with DNA, histone fraction F1 is appreciably more efficient in precipitating DNA from solution than are the other histone fractions, and Akinrimisi *et al.* have found that the various histone fractions differ in their binding affinity for DNA (ref. 21). It is possible, therefore, that fraction F1 or Ib plays a somewhat different part in nucleohistone than do the other fractions. Bonner and Huang<sup>5</sup> have suggested that the role of the histone fraction Ib is primarily to suppress genetic activity. However, experiments by Hindley<sup>22</sup>, by Murray<sup>15</sup> and by Huang *et al.*<sup>23</sup> on the selective removal of histones from nucleohistone show that fraction Ib is the most easily removed and its removal causes only a small increase in the priming of RNA synthesis by the residual nucleohistone, whereas removal of the fractions of higher arginine content causes a much more marked

Table 1.  $b_0$  VALUES FOR HISTONE FRACTIONS

increase in the priming of RNA synthesis. These results raise the possibility that the role of histone fraction Ib in native nucleohistone may be a structural one rather than that of a suppressor of genetic activity. In conclusion, we would stress the need for determination of the histone/DNA ratio of nucleohistone complexes (whether reconstituted nucleohistone, or residual nucleoprotein remaining after partial removal of histones) used as primers for DNA dependent nucleic acids synthesis.

### Amino-acid Composition and Partial Specific Volume of Citrate Oxaloacetate Lyase

STUDIES of the amino-acid composition of citrate oxaloacetate lyase (citrate lyase) from *Aerobacter aerogenes* were made using the pure enzyme prepared by methods previously described<sup>1,2</sup>. The amino-acid composition of the enzyme was determined using the technique of high-voltage electrophoresis to separate the amino-acids in a protein hydrolysate<sup>3</sup>. Hydrolysates of two quantities of enzyme (5.0 mg), by 'AnalaR' hydrochloric acid (6 N) in

Table 1. COLOUR YIELD OF THE AMINO-ACIDS ON A MOLAR BASIS BY THE CADMIUM NINHYDRIN METHOD

Isoleucine has been given a reference value of 100. Absorbancies of solutions were measured at 505 mμ.

sealed tubes at 110° for 24 h and 72 h, respectively, were prepared. The protein in the solution to be hydrolysed was estimated by the method of Hoch and Vallee<sup>4</sup>. The method of amino-acid separation and analysis was similar to that used by Atfield and Morris<sup>5</sup>, using a cadmium ninhydrin reagent. The apparatus was based on the general design of Gross<sup>6</sup>, with longer coiling plates, as favoured by Atfield and Morris<sup>5</sup>. The concentration of each amino-acid, after elution from the strip, was read from concentration-absorbancy graphs previously constructed using similarly treated standard solutions of amino-acids. Absorbancies were read on a Unicam SP 600 spectrophotometer at 505 mμ. The relative colour values of the cadmium ninhydrin complexes with individual amino-acids on a molar basis are given in Table 1; they show wide variations (cf. Helimann *et al.*<sup>7</sup>). Proline was estimated in the hydrolysate, and hydroxyproline shown to be absent, by estimation with cadmium isatin reagent.

From analyses of the two hydrolysates corrections were made for losses of some amino-acids (serine, threonine, arginine) on longer hydrolysis, while valine and isoleucine were incompletely released in the 24-h hydrolysis<sup>8</sup>. Tryptophan was only present in the longer hydrolysis but here showed good agreement (+ 9 per cent) with a spectrophotometric estimation by the method of Goodwin and Morton<sup>9</sup> using the formula derived by Beaven and Holiday<sup>10</sup> (cf. Hotchkiss<sup>11</sup>). The recovery of protein on the basis of amino-acids recovered was 102 per cent and 106 per cent, respectively in 24-h and 72-h hydrolysates. By the methods used no distinction could be made between cysteine and cystine, glutamic acid and glutamine, or between aspartic acid and asparagine. The amino-acid composition of citrate lyase thus determined is given in Table 2. The enzyme contains all the amino-acids commonly found in proteins and no unidentified compounds were evident. The partial specific volume,  $\bar{v}$ ,

of the protein calculated from this amino-acid composition<sup>13</sup> was 0.735, a value in good agreement with that assumed for molecular weight calculations in an earlier paper<sup>2</sup>.

We thank Mr. G. Tansley, of the University of Leeds, for construction of the high-voltage apparatus.

### Apparent Paradox in the Effects of Ethionine feeding on the Specific Activities of Rat Liver Glucose-6-phosphate Dehydrogenase and Pyruvate Kinase

It is generally agreed that protein and enzyme syntheses are depressed in the liver of ethionine-treated animals and that the mature female preferentially exhibits this diminution<sup>1,2</sup>. We were surprised, therefore (Fig. 1), to find a rise (200–300 per cent) of liver glucose-6-phosphate dehydrogenase activity in both sexes of ethionine-treated rats. On the other hand, 6-phosphogluconate dehydrogenase, which is the next enzyme in the shunt pathway sequence, is unaffected and pyruvate kinase of the Krebs cycle undergoes a decrease (50 per cent) in the liver of the female but not the male rat. In animals receiving both methionine and ethionine, no alterations from normal occurred. Accordingly, these diverse effects on enzyme activity of ethionine are now being reported to emphasize the complexity of enzyme phenomena in ethionine-treated animals.

The experimental conditions were as follows: both male and female Wistar rats, weighing approximately 100 g each, were maintained *ad libitum* on three separate diets. The control group received Purina chow, the ethionine groups received 0.5 per cent ethionine supplement in the chow diet, the ethionine-methionine group received 0.5 per cent ethionine and 5.0 per cent methionine supplement in the diet. Each group consisted of 6–10 animals. After 21 days of treatment, the animals were killed and bled, the livers were removed and chilled, and a 10 per cent homogenate was immediately prepared in 0.25 M sucrose–0.001 M EDTA solution. The supernatant fraction was obtained by centrifuging the homogenate for 30 min at 100,000g in a refrigerated Spinco model L preparative ultracentrifuge, and it was assayed for the activities of pyruvate kinase<sup>3</sup>, glucose-6-phosphate dehydrogenase and 6-phosphogluconate dehydrogenase<sup>4</sup>.

In the case of glucose-6-phosphate dehydrogenase, a sex difference in favour of a higher level in the normal female was observed<sup>5</sup>. However, ethionine-fed animals of both sexes exhibited an obvious and statistically significant ( $P < 0.01$ ) increase (Fig. 1) in activity of

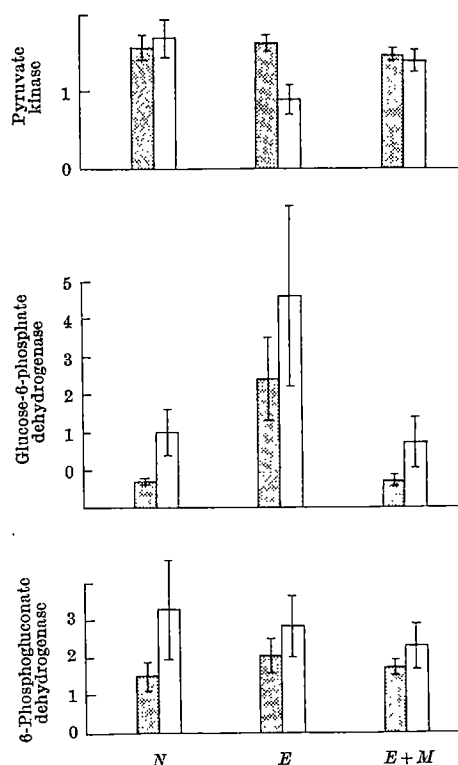

Fig. 1. Alterations in glucose-6-phosphate dehydrogenase, 6-phosphogluconate dehydrogenase and pyruvate kinase in relation to sex and ethionine treatment. The activities of G-6-P and 6-PG dehydrogenases are expressed as  $\mu$ moles of TPNH formed per mg of protein per h. Pyruvate kinase activity is expressed as  $\mu$ moles pyruvate formed per mg of protein per h. Data on male animals are shaded, those on female, unshaded. N, signifies normal control; E, ethionine-fed, and E+M, ethionine + methionine-fed, animals. Standard deviation is indicated by a vertical line in each column.

this particular dehydrogenase. The rise in glucose-6-phosphate dehydrogenase has also been observed in this laboratory<sup>6</sup> in mice on ethionine for only 4 days.

The fact that 6-phosphogluconate dehydrogenase is unaffected in this experiment makes it unlikely that a full activation of the 'shunt' pathway occurred. However, in unpublished experiments of longer duration than 21 days in rats and 4 days in mice, the activity of this enzyme also undergoes a significant elevation. It is reasonable to suggest, therefore, that the rise in glucose-6-phosphate dehydrogenase is the first indication of activation of the 'shunt' pathway, a route of metabolism around which much biochemical interest is now centred, particularly in relation to oncology.

In this connexion, reference should be made to investigations in proliferating and malignant cells<sup>7</sup>, in lymphatic leukaemia and Ehrlich tumour<sup>8</sup>, and in Novikoff hepatoma<sup>9</sup>. In transplanted hepatomata of varying degrees of deviation from normal liver, Weber and Morris<sup>10</sup> noted enhancement most frequently of the activities of glucose-6-phosphate dehydrogenase followed by 6-phosphogluconate dehydrogenase.

A different significance must be assigned to the reduction of pyruvate kinase. This event can be considered to partially explain the fall in liver ATP which has recently been suggested to be the cause of failure in protein synthesis<sup>11</sup>. In brief, since the ability of pyruvate kinase to catalyse the formation of ATP from ADP is greatly impaired, less ATP will accumulate. Moreover, in the female, ethionine is less rapidly metabolized than in the male, which would lead to a more complete trapping of ATP in the form of *S*-adenosylethionine as shown by Stekol *et al.*<sup>12</sup>. The combination of these two circumstances, loss of pyruvate kinase and less-rapid metabolism of ethionine in the female, may explain the sex difference in sensitivity to ethionine.

It may very well be that the activities of those enzymes, like pyruvate kinase, which decline in ethionine-treated females are part of an ATP-associated mechanism and that those enzymes the activities of which increase, such as glucose-6-phosphate dehydrogenase, belong to a group of enzyme proteins which may be undergoing *de novo* synthesis for different reasons. Support for the latter view is provided by the recent evidence for the stimulation of RNA synthesis and the increase of 'soluble' cysteine desulphydrase<sup>13,14</sup> in ethionine-treated rats.

Finally, a possible explanation for the present results is that in the course of time the population of cells in the livers of ethionine-treated animals<sup>1</sup> may be undergoing profound changes in both their type, number and state. Measurements of enzyme activity made on homogenates of such altered tissues may, therefore, be reflexions of these circumstances. Accordingly, it may be desirable in the future to identify the particular enzyme alteration with its cytoplasmic and cellular site.

We thank Prof. W. H. Fishman for his advice.

### Death in Mice induced by *Staphylococcus aureus* Protoplasm

THE most rational approach to treatment of an infectious disease is elimination of the infecting organism. Attempts to do this with antibiotics have not always been successful. Therefore, a characterization of the biochemical changes caused by the organism may result in biochemical replacements which can improve treatment. Previous work has shown that a profound derangement of carbohydrate metabolism can be induced in mice by living staphylococci<sup>1,2</sup>. When mice are challenged by a variety of routes, death occurs after a fixed number of cells has accumulated (as determined by total body counts) no matter in which portion of the body they multiply<sup>3,4</sup>. Since the staphylococcal cell is complex it would be desirable to fractionate it and produce death with known components. The first step in this process is to disintegrate the cell without damage to the enclosed chemicals and enzymes. We believe we have achieved this as the protoplasm used in the investigations to be reported was still able to coagulate citrated rabbit plasma at 37° C. The following investigations give some indication of the effect of fractionated *S. aureus* on male Swiss mice.

Coagulase-positive staphylococci were grown overnight in heavy culture on nutrient agar (Difco). The staphy-

A

B

Fig. 1. A, *Staphylococcus aureus* protoplasm (SAP) (phosphotungstic acid staining,  $\times 6,300$ ). B, Cell wall material from *Staphylococcus aureus* (uranyl acetate staining,  $\times 6,300$ ). Electron micrographs made by Dr. J. M. Layton

lococci used were from various clinical sources. They were washed off in distilled water (titre  $10^{10}$  cells/ml.), washed twice by centrifugation and resuspended in 100-ml. distilled water (about 150 mg/ml. dry weight). The Servall-Ribi Refrigerated Cell Fractionator was used to disrupt the cells. In this instrument a pressurized cell suspension is released at the orifice of a needle valve, whereby the cell walls are cracked and the protoplasm is released in a dispersed state<sup>4</sup>. A pressure of 40,000 lb./in.<sup>2</sup> was used and an orifice temperature of 0°–10° C was maintained. About 40–50 per cent of the cells were broken. The effluent was centrifuged at 13,000 r.p.m. at 2° C for 1 h in a Servall RC-2 centrifuge equipped with an SS-34 head to separate the unbroken cells and cell walls from the protoplasmic material. The supernatant was recentrifuged at the same speed and the sediments were discarded. Filtration through a 'Millipore' filter eliminated the last few organisms. All these procedures were carried out at 4° C except where otherwise indicated.

The protoplasmic material obtained by this procedure was a homogeneous, yellow, turbid, somewhat viscous fluid. No growth of micro-organisms in broth culture or on agar could be obtained aerobically or anaerobically. It was

coagulase-positive and  $\beta$ -haemolytic on sheep blood agar. Very few cell walls could be seen (Fig. 1). The material was coarsely granular microscopically. It passed through a HAWP 047.00 white, plain 'Millipore' filter. Heating at 80° C for 30 min destroyed its lethal properties. Preliminary results of analyses of this cytoplasm of *Staphylococcus aureus* (SAP) indicated the presence of 1 g/100 ml. of protein (Biuret method); reducing sugars 25 mg/100 ml. (Nelson-Somogyi method); 'polysaccharides' 10 mg/100 ml. (phenol sulphuric acid method) and total lipids 20–40 mg/100 ml. (gravimetric method). When subjected to free electrophoresis (Klett Tiselius barbiturate buffer pH 8.6, ionic strength 0.1) the protoplasm separated into three components. The major portion migrated at the rate of the  $\alpha$ -globulins, one minor component migrated at the rate of the albumin and a second more rapidly than the albumin of normal human serum. Further fractionation of these components and an examination of their biological activity are in progress<sup>5</sup>.

As little as 0.5 c.c. of the SAP (obtained from 10<sup>8</sup> whole *Staphylococcus aureus* cells) inoculated by the intraperitoneal route killed mice in 5–7 h (Table 1), the time required for death to occur when 10<sup>8</sup> whole staphylococcal cells were injected. We believe this was not due to intracellular mixture with exotoxins as our material was washed three or four times in distilled water before use. The mode of death from SAP was 'clinically' identical to that produced by live cells. That is to say, there was first a ruff-like erection of the neck fur, the animals bunched together, had an unsteady gait and appeared to be walking on tiptoe with a concavity of the buttocks; then they became dyspnoeic, humped their backs and showed spontaneous overactivity. Later they had running fits and a clonic convulsion, lost sphincter control and died. Mice killed by SAP were analysed biochemically and values obtained were essentially similar to those found in mice killed by whole staphylococci and they were significantly different from the biochemical values for normal mouse carcasses (Table 1). No staphylococci were obtained from cultures of the ground-up carcasses of animals killed with SAP. The results were reproduced many times with 5 out of 7 batches made at 40,000 lb./in.<sup>2</sup>. Death did not occur when protoplasm obtained after preparation by higher orifice pressure was used. These results were duplicated using other strains of coagulase-positive staphylococci. Death was also produced by SAP by the intramuscular and subcutaneous routes. In some instances the material was dermonecrotic (Table 2).

The induction of death by non-replicating elements of *Staphylococcus aureus* cells provides a new approach to

investigating the cause of death from staphylococcal infection and to differentiate host from organismal chemical effects<sup>7</sup>.

## A Haemoprotein from the Lipid of Peanuts

MUCH literature exists on the effects of haematin compounds on the oxidation of unsaturated fats and fatty acids in emulsions and colloidal suspensions<sup>1-3</sup>. We wish to report a naturally occurring haematin protein found in the lipid fraction of peanuts and other seeds.

The absorption spectrum of an intact peanut cotyledon (Fig. 1 A, solid curve) shows a prominent absorption band at 635 m $\mu$ . Similar bands in the 640-m $\mu$  region (635–645 m $\mu$ ) have been found, to a lesser extent, in the absorption spectra of intact lima beans, soybeans, wheat, oats, barley, watermelon seeds, and yeast<sup>4</sup>. Soaking the peanuts in 0.1 M KCN for 15 min causes the loss of the 635-m $\mu$  band and the appearance of a broad absorption band in the 540-m $\mu$  region (Fig. 1 A, dashed curve). The 635-m $\mu$  pigment is distributed throughout the cotyledons so that the cyanide must penetrate the whole seed. The sensitivity of the 635-m $\mu$  band to cyanide distinguishes the material from protochlorophyll, which has an absorption band in the 630- to 650-m $\mu$  region<sup>5</sup>. On the basis of the absorption spectra<sup>4</sup>, the 635-m $\mu$ -absorbing material in intact seeds and yeast was ascribed to a ferric haematin compound. The present paper reports the extraction and partial purification of this material from peanut seeds.

Both dry and imbibed peanuts were ground and extracted with 0.4 M sucrose, and the extract was fractionated by differential centrifugation. The various fractions were examined with a spectrophotometer which could accommodate dense, highly scattering samples such as intact seeds and turbid media<sup>6</sup>. The only fraction that showed an appreciable amount of the 635-m $\mu$ -absorbing material was the white lipid layer collected from the top of the centrifuge tube (Fig. 1 B). The lipid also showed a carotene-like absorption band at 480 m $\mu$ . The 635-m $\mu$  pigment remained with the residue after thorough extraction of the lipid with methanol, acetone, ether, chloroform or butanol and the extraction did not render the pigment soluble to aqueous systems. The absorption spectrum of the residue from the acetone extraction is shown in Fig. 1 C. Removal of the carotene-like pigment unmasked a broad absorption band in the 500-m $\mu$  region. A part of the

Fig. 1. *A*, solid curve, absorption spectrum of intact peanut cotyledon. Dashed curve, absorption spectrum of same cotyledon after soaking in 0.1 M KCN for 15 min; *B*, absorption spectrum of lipid fraction collected from peanut homogenate; *C*, absorption spectrum of residue from acetone extraction of the lipid; *D*, solid curve, absorption spectrum of digitonin extract (2 per cent digitonin for 24 h) of the acetone powder of the lipid.  $\text{CaCO}_3$  powder was added to the extract to increase light scatter. Dashed curve, absorption spectrum of the same sample after addition of pyridine and sodium hydrosulphite

635-mμ-absorbing material could be solubilized by extracting the acetone powder with 2 per cent digitonin. The solid curve in Fig. 1 *D* shows the absorption spectrum of the digitonin-solubilized material to which enough  $\text{CaCO}_3$  was added to make a thick white paste. The  $\text{CaCO}_3$  makes the light-scatter more comparable to the other samples and increases the intensity of the 635-mμ absorption band 10- to 20-fold by increasing the optical path-length<sup>7</sup>. The pigment could also be solubilized from an acetone powder by 4 M urea, but reprecipitated when the urea was removed by dialysis.

The absorption spectrum of the solubilized material is very similar to that of catalase, peroxidase and methaemoglobin<sup>8</sup>. With the solubilized pigment, cyanide, fluoride and azide (pH 4.2) all form complexes which destroy the 635-mμ absorption band. Carbon monoxide, which combines with ferrous but not ferric haematin compounds<sup>8</sup>, has no effect on the absorption spectrum. The pigment is not reduced by sodium hydrosulphite or potassium borohydride, which is typical of a catalase, but not of a peroxidase or methaemoglobin<sup>8</sup>. The addition of sodium hydrosulphite plus pyridine gives a typical haemochromogen spectrum (dashed curve, Fig. 1 *D*).

The prosthetic group could be extracted from the residue of chloroform extracted lipid with acid acetone (500 acetone : 1 conc. HCl). An equal volume of ether was added to the extract followed by the addition of NaCl to 5 per cent, with shaking. The ether layer was then removed and concentrated by evaporation. Fig. 2 shows

the absorption spectrum of the concentrated ether extract plus  $\text{CaCO}_3$  and the spectrum obtained by adding sodium hydrosulphite and pyridine. These spectra indicate that the prosthetic group is protohaem.

The concentration of the 635-mμ-absorbing material in the lipid fraction was estimated by assuming an extinction coefficient of a typical catalase or peroxidase and determining experimentally the effect of the light scatter on the intensity of the absorption band. The absorption band resulting from the addition of a small volume (10 μl.) of a methanolic solution of chlorophyll to the lipid was intensified 5.6 times by the light scatter in the lipid (assuming that the extinction of chlorophyll is the same in lipid as it is in methanol). Taking the absorbancy of the 635-mμ absorption band of the 6-mm-thick sample of lipid (Fig. 1 *C*) to be 0.3, the scatter intensification factor to be 5.6, and the molar extinction coefficient to be  $10 \text{ mM}^{-1} \text{ cm}^{-1}$ , which is typical for peroxidase or catalase<sup>8</sup>, the concentration of the 635-mμ pigment in the lipid was  $9 \times 10^{-6} \text{ M}$ .

The protein content of a digitonin-solubilized solution, measured by the Biuret test after dialysis and precipitation of the protein with 10 per cent trichloroacetic acid, was 10 mg/ml. The haem content, estimated from the absorption spectrum of the solution after addition of  $\text{CaCO}_3$ , assuming an extinction coefficient of  $10 \text{ mM}^{-1} \text{ cm}^{-1}$  and a scatter intensification of 10, was  $5 \times 10^{-6} \text{ M}$ . This gives a ratio of  $2 \times 10^{-6} \text{ g}$  protein per mole haem, which is probably correct to within an order of magnitude. The strong affinity of the protein for the lipid and the partial solubilization by digitonin suggest that the haem is attached to a lipoprotein. The digitonin-solubilized material showed moderate catalase activity as assayed by potassium permanganate titration<sup>9</sup> and essentially no peroxidase activity by the guaiacol test<sup>9</sup>. The lipoprotein, however, may not catalyse a specific reaction *in vivo*. In general, the action of haematin compounds in the oxidation of unsaturated fats is quite non-specific<sup>1,2</sup>.

In order to ascertain how germination affected the 635-mμ pigment, absorption spectra were measured on intact peanut cotyledons from seedling plants which were germinated in the dark. For the first 6 to 7 days' imbibition, the magnitude of the 635-mμ absorption band remained constant to within the limits of sample reproducibility. During this time, there was no shrivelling or visible deterioration of the cotyledons even though the plants had grown to a height of 10-15 cm. Estimates of the lipid content of the cotyledons, made by grinding 10-g samples of cotyledons in 0.4 M sucrose and collecting the lipid by centrifugation, also indicated little if any loss of lipid during this period. (The lipid decreases much earlier in peanuts that are germinated in the light, but the

Fig. 2. Absorption spectra of the prosthetic group split from the residue of a chloroform extract of the lipid: solid curve, absorption spectrum of extracted prosthetic group; dashed curve, absorption spectrum after addition of pyridine and sodium hydrosulphite

accumulation of chlorophyll in the cotyledons obscures the 635-m $\mu$  absorption band.) After 7 days, however, the lipid content of the dark-germinated cotyledons decreased abruptly, the cotyledons began to shrivel, and the magnitude of the 635-m $\mu$  absorption band decreased. Thus, the haemoprotein appears to be broken down as the lipid is utilized. It should be noted that when haematin compounds catalyse the oxidation of unsaturated fatty acids they are destroyed<sup>1,2</sup>, presumably through reactions with lipid peroxides.

Lewis and Wills<sup>3</sup> showed that haemoglobin could either catalyse or inhibit the oxidation of linoleic acid, depending on the ratio of the two compounds. At a concentration of  $1.2 \times 10^{-6}$  M, haemoglobin inhibited the oxidation of 0.017 M linoleic acid, while at a concentration of  $4 \times 10^{-6}$  M it was a strong catalyst. With  $5 \times 10^{-3}$  M linoleic acid, however,  $4 \times 10^{-6}$  M haemoglobin inhibited the oxidation. The relatively high concentration of haemoprotein in peanut fat suggests that it could have a protective effect, particularly in preventing the peanut from becoming rancid during long periods of storage. However, if the degree of lipid unsaturation increased during germination, the haemoprotein might change from being an inhibitor to being a catalyst of lipid oxidation.

## Changing Base Ratios in RNA of Developing Tissues of *Xenopus laevis*

THE new forms of RNA synthesized during embryonic development of the South African clawed toad, *Xenopus laevis*, have come under investigation recently by Brown and Gurdon<sup>1</sup> and are discussed more fully by Brown and Littna<sup>2</sup>. Since their work was concerned only with events in the embryo as a whole, we have undertaken a study of possible differences in the new forms of RNA synthesized in different tissue primordia of this species. In the preliminary work to be reported here, the nucleotide composition of the total acid-insoluble RNA extracted both from whole embryos and from ectoderm undergoing three different courses of differentiation—into neural plate, neural crest and epidermis—has been analysed. Although data published by Yeas<sup>3</sup> indicated that different tissues of the adult rat do not show any significant differences in their RNA composition, there have been several other reports<sup>4-7</sup> of altered base ratios in RNA of tissue cells undergoing special phases of modified protein synthesis in response to external stimuli. It seemed likely, therefore, that embryonic tissues responding to stimuli such as neural induction might also show some alterations of RNA base ratios. As will be reported here, RNA extracts both from whole embryos and from the isolated ectoderm do, in fact, exhibit some changes in base ratios, which are of general interest in view of the protein syntheses known to be occurring at these stages of development.

For the analyses, samples of 12 whole, demembrated embryos or 80 ectoderm pieces were collected in cold 80 per cent ethanol, then extracted for 1 h in 200  $\mu$ l.

0.3 N perchloric acid, followed by a minimum of 4 h in two changes of 400  $\mu$ l. of cold 3:1 ethanol:ether<sup>8</sup>. The residues were hydrolysed for 16–24 h in 200  $\mu$ l. 0.35 N potassium hydroxide solution at 37° C (ref. 9). The pH of the hydrolysate was adjusted to 1.0 with 6 N perchloric acid and the resultant precipitate removed by centrifugation. The supernatant, after pH adjustment to 3.5 and volume adjustment to equivalence with the other samples in the same experiment, was applied in 30- $\mu$ l. aliquots to strips of Whatman No. 1 filter paper, 4  $\times$  28 cm., for electrophoretic separation of the mononucleotides. 0.15 M formate buffer, pH 3.5, was used<sup>10</sup> and a current of 3.5 m.amp/cm width was applied for 10 h. After marking the positions of the absorption bands under ultra-violet light, they were cut out and eluted into 0.01 N hydrochloric acid. Absorption spectra of the eluates were plotted between 220 and 300 m $\mu$ . The spectra corresponded to those published by Beaven, Holiday and Johnson<sup>11</sup>, and these authors' absorptivity coefficients were used to estimate the concentrations of the nucleotides and hence their molar ratios.

Table 1 gives the results of analyses of RNA from whole embryos, and Table 2 gives the analyses of RNA from the different types of ectoderm at stages from gastrula to tailbud. Fig. 1 shows diagrammatically how the embryos were dissected to obtain presumptive neural plate, neural crest and epidermis. The vertical lines in Tables 1 and 2 indicate statistically significant changes in base ratios.

Moles/100 moles. Means, with standard errors, from 5 samples.

\* Includes neural crest.

† Only one sample available for analysis.

The data of Table 1 show that there are marked relative increases in cytidine (CMP) at the onset of gastrulation and neurulation, respectively, and also smaller increases during cleavage stages. At gastrulation and early neurulation, the guanine ratio decreases. It is interesting that such marked changes should occur at these particular stages when, according to Brown and Littna's recent investigations<sup>2</sup>, new ribosomal RNA is synthesized. Brachet *et al.*<sup>12</sup> and Denis<sup>13</sup> have also concluded from an entirely different approach, using actinomycin D treatment, that these two phases, as well as that of late cleavage, are critical for the synthesis of DNA-dependent RNA. However, the very high cytidine content of RNA featured here has not been observed by any of these workers. From the data on isolated ectoderm (Table 2)

Fig. 1. Diagram to show the origin of tissues analysed

it is clear that the neural plate, in particular, exhibits a marked increase in molar concentration of cytidine at the early neurula stage. There is at the same time a marked decrease in relative concentration of adenylic acid in this tissue. The epidermis, by contrast, shows a slight relative decrease in cytidine and increase in guanidine, at the early neurula stage. The most striking base ratio changes in epidermis occur between early and late gastrula stages, however: there is a very large increase in guanidine, matched by a decrease in uridine. In the neural crest ectoderm, the uridine ratio becomes higher than in the other two tissues at the tailbud stage, and one is led to speculate whether this may be due to an increased proportion of uridine triplets coding for phenylalanine uptake which is known<sup>14</sup> to be essential for the differentiation of neural crest cells and for melanin synthesis.

These findings are of general interest since they show that certain clear differences in the ribonucleotide composition of total RNA already arise in the ectoderm as it diverges along three different paths of differentiation in the early embryo. The significance of these differences, in terms of the kinds of RNA being synthesized in these tissues, is now under investigation using <sup>32</sup>P-labelling and sucrose density-gradient separation methods.

## PHYSIOLOGY

### Effect of $\alpha$ -Melanocyte-stimulating Hormone and a Minute Trauma on the Ciliary Processes of the Rabbit's Eye

MELANOCYTE-stimulating hormone (MSH) and other hypophyseal polypeptides have been shown to exert an effect on the permeability of the blood aqueous barrier of the rabbit's eye<sup>1,2</sup>. This effect has certain similarities to a localized trauma on the eye (such as the increase in flare, fluctuation in intra-ocular pressure), but it is not, unlike the traumatic effect, diminished by local anaesthetics<sup>3</sup>. Considerable interest is attached to a comparison of the histological changes after MSH and trauma. In a group of 18 animals, a minute trauma was induced in 5 of them by infra-red irradiation<sup>4</sup> on the upper part of the iris, a subcutaneous injection of 10  $\mu$ g synthetic  $\alpha$ -MSH (Schwyzer) was given to 7, and 6 acted as controls (as also did the contralateral eyes of the first group). The eyes were enucleated in the trauma group 30 min after the trauma, in the MSH group 90 min after

Fig. 1. (A) Ciliary processes (cp) and iris (i) from normal eye; (B) from traumatized eye, with 'Greeffsche Blasen' (G); (C) from MSH-treated animal ( $\times 86$ )

the injection. Following freeze-drying and fixation in Carnoy's solution the tissues were embedded in paraffin, sectioned<sup>5</sup>, and stained with haematoxylin-eosin.

The following are the results of our histological examinations (see Fig. 1): (1) In both the trauma and MSH groups there was, without exception, a swelling of the anterior ciliary processes, an interstitial oedema and possibly a dilatation of the small intraciliary vessels. Typical 'Greeffsche Blasen' with splitting of the two layers of the secretory epithelium<sup>6</sup> were observed to a similar extent in both groups. In the 17 normal eyes no such changes were seen.

(2) In 7 eyes from MSH-treated animals, where no flare effect occurred, there was still a marked swelling of the ciliary processes, but no 'Greeffsche Blasen' were found.

(3) The trauma effect was observed around the whole circumference of the ciliary body but more excessively on the upper part, that is, behind that part of the iris treated with infra-red irradiation.

(4) No changes in the iris, not even in its irradiated part, or in the melanocytes of the iris and ciliary body could be observed in any of the eyes.

Although recent investigations<sup>7</sup> have shown that MSH causes a series of general effects in the rabbit, for example, a decrease in the blood pressure and dilatation of the peripheral vessels, there is still no evidence that the permeability disturbance should be a generalized effect.

## Permeability Effects of $\alpha$ -Melanocyte-stimulating Hormone

$\alpha$ -MELANOCYTE-stimulating hormone ( $\alpha$ -MSH) induces an increased permeability of the blood-aqueous barrier of the rabbit eye<sup>1,2</sup>. It has been shown in the preceding communication that  $\alpha$ -MSH produces a swelling of the ciliary processes with an interstitial oedema in this species. Since the permeability disturbance might be part of a more generalized effect, it was considered worthwhile investigating whether or not there was also an increased leakage of proteins through other barriers.

<sup>125</sup>I-labelled human serum albumin (Radiochemical Centre, Amersham) was given intravenously 30 min after a subcutaneous injection of 10  $\mu$ g/kg synthetic  $\alpha$ -MSH (ref. 3) (supplied by Ciba, Basle) in 0.9 per cent sodium chloride to 12 pigmented rabbits and after the same volume of 0.9 per cent sodium chloride had been given to 5 pigmented rabbits (controls). Blood samples were collected at 30-min intervals. The aqueous flare response<sup>2</sup> was taken as proof of the local permeability disturbance of the eye after the  $\alpha$ -MSH and was estimated roughly by means of focal illumination before and 2 h after the injection. 2.5 h after the  $\alpha$ -MSH injection the rabbits were killed, their eyes enucleated and dissected essentially as described previously<sup>4</sup>. Small tissue samples were also collected from various organs. The radioactivity of the blood and tissue samples was determined.

The radioactivity in counts per minute of the tissue samples was divided by the radioactivity in c.p.m./ $\mu$ l. plasma in the blood sample obtained immediately before the animals were killed. This gave a figure for the apparent

Table 1. THE RELATIVE FALL IN BLOOD RADIOACTIVITY AFTER AN INJECTION OF <sup>125</sup>I-ALBUMIN

In animals showing an aqueous flare response after the injection of  $\alpha$ -MSH, R; in animals not responding with aqueous flare, NR; and in controls, C. Arithmetic means  $\pm$  the standard error of the means. The radioactivity of the first blood sample is 1.00

Time after <sup>125</sup> I- alb. inj.	4 min	30 min	60 min	90 min	120 min
R	1.00	0.90 $\pm$ 0.0086	0.83 $\pm$ 0.0114	0.79 $\pm$ 0.0125	0.77 $\pm$ 0.0191

Table 2. THE APPARENT PLASMA CONTENT OF THE ANTERIOR UVEA AND THE CHOROID PREPARATIONS AND IN 1 ML. AQUEOUS HUMOUR

In animals responding with increased aqueous flare to  $\alpha$ -MSH, R; in non-responsive animals, NR; and controls, C. Arithmetic mean  $\pm$  the standard error of the mean

	The apparent plasma volume ( $\mu$ l.)		
	Anterior uvea	Choroid	1 ml. aqueous humour
R	33.5 $\pm$ 2.83	6.03 $\pm$ 0.66	265.2 $\pm$ 33.9
NR	7.1 $\pm$ 0.64	4.40 $\pm$ 0.32	3.4 $\pm$ 0.70
C	7.1 $\pm$ 1.27	4.81 $\pm$ 0.26	6.6 $\pm$ 2.90

plasma content, which included 'plasma' both from intravascular and extravascular compartments.

In 6 of the 12 rabbits which had been given MSH there was a pronounced increase in aqueous flare. In the remaining 6 and in the control group no aqueous flare was detected.

We found no increased rate of loss of <sup>125</sup>I-albumin from the intravascular compartment (Table 1). In the 6 rabbits where the aqueous flare was prominent, the albumin content of the aqueous humour was very much increased as compared with the 6 test rabbits in which no flare was observed and with the controls (Table 2). The apparent plasma content of the anterior uvea was greatly increased, while no such effect was observed in the choroid as shown in Table 2. No similar change in apparent plasma content could be found in the urine, the gall, the brain, the liver, the kidneys, the lung, the spleen, the intestines, the suprarenals or the muscles.

It thus seems that the permeability increasing effect of the melanocyte-stimulating peptides is rather specific for the eye. However, it should be pointed out that a rise in the vasomotor tone of the small veins might be of importance in the increased protein transfer.

The present work was supported by a research grant (B 3060) from the National Institutes of Neurological Diseases and Blindness, U.S. Public Health Service.

## The Ussing Relationship and Chemical Reactions: Possible Application to Enzymatic Investigations

It may not be widely appreciated that the Ussing flux ratio relationship<sup>1,2</sup> is applicable to chemical reactions in general. It is possible that measurement of such flux ratios may yield information about reaction intermediates, particularly in enzymatic processes, but perhaps also in catalytic, heterogeneous, and other chemical reactions.

To demonstrate the relationship of the Ussing criterion to a typical chemical reaction it is convenient to use an argument based on induced transport<sup>3</sup>. Consider the reversible reaction:

and let  $A$  and  $C$  be labelled in such a way that all the labelling from  $A$  appears in product  $C$  and vice versa. Then, the free energy change for the conversion of  $\Delta m$  moles of radioactive  $A$  into  $C$  is:

$$\left[ RT \ln \frac{f_C k_C C_C f_D C_D}{f_A k_A C_A f_B C_B} + nEF + RT \ln K \right] \Delta m$$

where  $C_A$ ,  $C_B$ ,  $C_C$  and  $C_D$  are the concentrations and  $f_A$ ,  $f_B$ ,  $f_C$  and  $f_D$  are the activity coefficients of  $A$ ,  $B$ ,  $C$  and  $D$ .  $k_A$  and  $k_C$  are the specific activities of  $A$  and  $C$ .  $E$  is the electrical potential difference between  $A$  and  $B$ , and  $C$  and  $D$ ,  $n$  is the net number of electrical charges transferred from left to right in equation (1) and  $RT$  and  $F$  have their usual significance. If  $A$ ,  $B$ ,  $C$  and  $D$  are present in the same solution  $E$  is, of course, zero, but the electrical potential may be relevant in an electrode reaction or if  $A$  and  $B$ , and  $D$  are separated by a membrane.  $K$  is the equilibrium constant. The expression follows from a consideration of the entropy changes based on the probabilities of the systems and the assumption that the total energies are unaffected by the isotopic composition. Let there be equilibrium with respect to the isotopic molecules of  $A$  and  $C$ . Then:

$$RT \ln \frac{f_C k_C C_C f_D C_D}{f_A k_A C_A f_B C_B} + nEF + RT \ln K = 0 \quad (2)$$

If  $m_{A \rightarrow C}$  and  $m_{C \rightarrow A}$  are the fluxes for the conversion of  $A$  into  $C$  and vice versa, it is also possible to write:

$$\text{flux of radioactive } A \text{ to } C = k_A m_{A \rightarrow C}$$

and:

$$\text{flux of radioactive } C \text{ to } A = k_C m_{C \rightarrow A}$$

Since there is equilibrium between the radioactive  $A$  and  $C$  molecules the two fluxes should be equal so that:

$$k_A m_{A \rightarrow C} = k_C m_{C \rightarrow A} \quad (3)$$

From equations (2) and (3):

$$\frac{m_{A \rightarrow C}}{m_{C \rightarrow A}} = \frac{f_A C_A f_B C_B}{f_C C_C f_D C_D} \cdot \frac{1}{K} e^{nEF/RT} \quad (4)$$

If equation (4) is not obeyed there must be directly or indirectly some interaction between the radioactive and non-radioactive molecules of  $A$  and  $C$  in such a way that some energy is exchanged. If the left-hand side of equation (4) is less than the right-hand side the situation is equivalent to 'exchange diffusion'<sup>1</sup> and either the conversion of one  $A$  molecule to a  $C$  molecule must facilitate the conversion of another  $C$  molecule to an  $A$  molecule, or the conversion of an  $A$  molecule to a  $C$  molecule must interfere with the conversion of another  $A$  molecule to a  $C$  molecule (but not at the same time interfering with the back reaction). A molecular 'shuttle' could give rise to 'exchange diffusion' by either of these processes. Consider an enzyme catalysing a reaction  $A \rightleftharpoons B$  and suppose that the enzyme exists in two forms  $E_A$  and  $E_B$  so that:

and:

Then it may be shown that, if reaction (6) is at all rate-limiting, exchange diffusion will occur: this is most likely when the concentrations of  $A$  and  $B$  are high. With the bimolecular reaction shown in equation (1) the situation is more complicated. Let the two forms of the enzyme be denoted by  $E_A$  and  $E_C$  then one possible sequence is:

If reaction (10) is at all rate-limiting the interconversions of  $A$  and  $C$ , and  $B$  and  $D$  will both show 'exchange diffusion' and this will be most marked when the concentrations of  $A$ ,  $B$ ,  $C$  and  $D$  are high. If reaction (10) is not rate-limiting, 'exchange diffusion' will not occur between

$A$  and  $C$ ; but if either or both of the reactions (7) and (9) are rate-limiting, exchange diffusion will occur between  $B$  and  $D$  and will be most apparent when the concentrations of  $B$  and  $D$  are high. When  $A$  and  $B$  combine with the enzyme in random order it is necessary to consider all possible pathways: overall exchange diffusion will occur if one or more pathways show the phenomenon. Other reaction sequences are possible, for example:

where  $E_A$ ,  $E_B$ ,  $E_C$  and  $E_D$  are different forms of the enzyme. If reactions (12), (13) or (14) are at all rate-limiting there will be exchange diffusion between  $A$  and  $C$ ; and exchange diffusion will, of course, occur in extreme form if  $B$  and  $D$  are omitted.

If the left-hand side of equation (4) is larger than the right-hand side the situation is equivalent to the 'long pore effect', and the conversion of an  $A$  molecule to a  $C$  molecule must either facilitate the conversion of another  $A$  molecule to a  $C$  molecule or interfere with the conversion of a  $C$  molecule to an  $A$  molecule. Two molecular mechanisms might show this effect. Thus it might occur if more than one molecule of substrate had to become attached to the enzyme before reaction could occur to give more than one molecule of product (cf. polyvalent carriers)<sup>2</sup>. Alternatively there might be a sequence of reaction sites on the enzyme that the substrate had to traverse, and the intermediate products might be unable to leave the enzyme. The effect in the latter case would be apparent at high concentrations and would be the equivalent of diffusion through a long pore<sup>4</sup>.

The test proposed in this communication is related to the measurement of isotope exchange rates at equilibrium<sup>6-9</sup>. The interpretation of exchange rates, however, may be complicated by inhibition (which may be non-specific) of the enzyme by the substrates whereas such inhibition will not affect the flux ratio. The flux ratio should give some indication of the rate-limiting steps and the order of addition of the reactants. If the reaction steps are known some estimate of the rate constants and affinity constants should also be possible.

It will be noted that the enzymes have been depicted as existing in two or more forms. The assumption that the free enzyme exists in only one form (or that the different forms rapidly interconvert) does not necessarily seem to be justified. It is conceivable that an activation energy for the interconversion of the free forms of the enzyme might allow the activation energy for the other reaction steps to be smaller. To show 'exchange diffusion' for an isomerizing enzyme (reaction (6)) would be good evidence of the existence of two forms of the enzyme unless special reactions purely for exchange<sup>9-12</sup> are postulated.

## Reverberatory Inhibitory Circuits in the Lateral Geniculate Nucleus of the Rat

A PROMINENT feature of synaptic transmission through the lateral geniculate nucleus (LGN) in the cat<sup>1-3</sup> and in the rat<sup>4</sup> is the large and prolonged depression of transmission which occurs following a single shock to the optic nerve. In the work reported here an attempt was made to discover the cause of this depression.

Extracellular records have been obtained from single cells of the LGN in the rat, anaesthetized with paraldehyde or pentobarbital, using glass microcapillary electrodes filled usually with 3 M KCl. Electrical stimuli were applied to the contralateral optic nerve or the ipsilateral visual cortex. Cells were recognized by the criteria of Bishop, Burke and Davis<sup>5</sup>. The cells fall conveniently into two groups:

(1) *P* cells, believed to be the principal cells of the LGN, constitute 88 per cent of the 255 cells investigated, and have the following characteristics. In response to a single shock to the optic nerve they discharge once at short latency (mode 3.2 msec, 207 cells; Fig. 1*a*) and usually later also in a series of bursts (up to 6), occurring at more or less regular intervals (Fig. 1*b*). The number of discharges per burst is usually 2-4 and the interval between bursts ranges from 100 to 1,360 msec. The total duration of the discharge is usually 1-2 sec, but some cells continue to fire for as long as 5 sec. In many cells the longer intervals are multiples of the shortest interval, suggesting an underlying rhythm which does not always fire off the cell. *P* cells are also discharged by cortical stimulation and in most cases either at short latency or with a wave-form characteristic of antidromic invasion<sup>6</sup> or both. Furthermore, the single antidromic response is then followed by a series of bursts in a pattern which is closely similar to that produced by orthodromic activation. Finally, it is an important point that the bursts can usually be elicited by stimuli, either orthodromic or antidromic, which are sub-threshold for the early response.

(2) *I* cells, believed to be inhibitory interneurons, represent 12 per cent of all cells, with the following characteristics. In response to a single shock to the optic nerve they discharge at short latency with a burst of about 10 spikes (Fig. 1*c*). The mode of the latencies of the first spike is 4 msec (30 cells). The first burst is then followed by similar bursts at intervals comparable with those in the pattern of *P* cell firing (Fig. 1*d*). *I* cells are also discharged by cortical stimulation, but in no case does the extracellular wave-form indicate antidromic invasion<sup>6</sup>.

Fig. 1. Extracellular records from single LGN cells in the rat. *a* and *b*, *P* cell discharge; *c* and *d*, *I* cell discharge, both in response to a single shock to optic nerve. *a* and *c*, short latency discharge (time calibration 5 msec between the records). *b* and *d*, short latency discharge followed by later bursts, on slower timebase (time calibration 200 msec between the records). Voltage calibration 1 mV, upper applies to *a* and *b*, lower to *c* and *d*.

Fig. 2. Recovery curve of postsynaptic field (multineuronal) response in LGN of rat. Two stimuli were applied to the optic nerve, the first (conditioning) supramaximal for the fast group of optic fibres (ref. 4), the second (test) about 50 per cent maximal, and the interval between the two systematically varied. The points on the graph plot the amplitude of the conditioned test response as a percentage of the unconditioned test response. The bars in the lower part of the figure indicate the durations and times of occurrence of the short latency response in 25 *I* cells. Arrows at the end of some bars indicate that the burst continued for an undetermined time. The larger arrow to the right indicates the earliest commencement of a second burst in any *I* cell.

A typical example of the time-course of depression of the field response in the LGN following a single shock to the optic nerve is shown in Fig. 2. A similar curve may be obtained if the conditioning stimulus is applied to the cortex and the test stimulus to the optic nerve. Curves have also been obtained for single *P* cells in which the proportion of times the cell fired was plotted against the interval after the conditioning shock; in some cells inhibition was demonstrated after a conditioning stimulus insufficiently strong to evoke the response of the cell itself. The curves show considerable variation in time-course from one cell to another, a few cells recovering fully in about 40 msec, others only after 5 sec. 10 per cent of *P* cells show an early recovery, between 3 and 10 msec, and subsequent depression similar to the field recovery curve. These curves show that the *P* cell recovers at or somewhat before the time of the first burst and is usually again depressed (even if the first burst fails to appear), although to a smaller extent, before recovering once more. Several oscillations in the recovery curve are frequently seen. In the field recovery (Fig. 2) the oscillations due to individual *P* cell recovery tend to disappear because of asynchrony. Recovery curves of *I* cells are remarkably similar to each other; almost all cells recover fully in about 160 msec and thereafter the curves show no oscillation.

It is unlikely that this inhibition is due to presynaptic inhibition<sup>7,8</sup> because (a) the excitability of the optic nerve terminals in the LGN is increased only to a very small degree following strong repetitive stimulation of either optic nerve or cortex (testing by the method of Wall<sup>9</sup>); (b) a synaptic potential<sup>10</sup> appears in response to a second shock at the shortest interval that can be measured (about 3.2 msec) and reaches a maximum height in less than 20 msec, thereafter not significantly altering in magnitude until the spike reappears; (c) the inhibition is equally effective on the injury discharge of a cell caused by mechanical stimulation from the electrode.

These facts, and some others to be mentioned below, are most easily explained by supposing that the *P* cells are monosynaptically activated from the optic nerve and project to the visual cortex (that is, are principal cells), that collaterals of these cells synapse with the *I* cells which in turn project back on to the *P* cells; that the prolonged discharge of the *I* cells causes a hyperpolarization of the *P* cells. This recurrent inhibition would be identical with that produced on the spinal motoneurone via the Renshaw cell<sup>11</sup>. It is further postulated that, as the hyperpolarization of the *P* cell wanes, the cell tends to

discharge again, possibly because of post-anodal exaltation. This second discharge of the *P* cells in turn re-excites the *I* cells and so the process continues. However, initially the *P* cells discharge synchronously and so the discharge of the *I* cells is also fairly synchronous, producing a deep depression. The relationship of the *I* cell discharge to this inhibition is shown in Fig. 2. The second and succeeding bursts become more and more asynchronous so that the hyperpolarization of the *P* cells presumably becomes smaller although more prolonged, with the result that the *P* cells cease to discharge and then in turn so do the *I* cells. As the *I* cell discharge becomes asynchronous and individual *I* cells cease to discharge, the overall level of inhibition falls off, as shown in the field recovery curve (Fig. 2).

This hypothesis is very similar to that proposed by Andersen and Eccles<sup>12</sup> for the ventrobasal complex of the thalamus, the only difference being that in this nucleus the postsynaptic inhibition appears to be due to a single inhibitory postsynaptic potential (IPSP)<sup>13</sup>. It would seem also that our explanation would apply to the LGN in the cat since recurrent collaterals have been described there<sup>14-16</sup>, rhythmic bursts may be elicited either from optic nerve<sup>17,18</sup> or cortex<sup>18</sup>, and after-positivity and associated inhibition follow both methods of stimulation<sup>19</sup>. A grouping into *P* and *I* cells may also be possible<sup>20</sup>, although the distinction is not so clear-cut in the cat because the *P* cells commonly discharge 3 or 4 times at short latency while the proportion of *I* cells appears to be lower than in the rat. Recurrent inhibition of this type has also been described in the cerebral cortex<sup>21</sup> and hippocampus<sup>22</sup>.

Since the recovery of the *I* cells to optic nerve stimulation is presumed to be dependent on the recovery of the *P* cells, the fairly uniform recovery of the *I* cells at about 160 msec suggests that they all receive a fairly similar innervation and therefore probably a strong convergence from the *P* cells. This conclusion is supported by the fact that strong inhibition can be produced in the LGN even by weak stimulation of the optic nerve or visual cortex.

As suggested by Andersen and Eccles, this type of reverberatory circuit may provide the basis for slow rhythms throughout the brain. We agree also with their suggestion that the inhibitory discharge is widely distributed to the principal cells, and would add the suggestion made in the preceding paragraph that there is also a strong convergence of *P* cells on to *I* cells. This circumstance would provide an explanation for spindles in the EEG record. If we suppose that in a period of quiescence one or a few *P* cells can be excited, their discharge will trigger off a comparatively large number of *I* cells, which in turn will hyperpolarize a still larger number of *P* cells and these will discharge on their recovery phase, leading to still more widespread activation of *I* cells. In this way the process could wax to a maximum and then wane again, for the reasons given earlier. This scheme might also explain why Bishop and Davis<sup>18</sup> obtained rhythmic slow waves in the LGN of the cat to optic nerve stimulation even when synaptic transmission had been blocked. If only a few *P* cells remain unblocked the process could 'spindle'. It is supposed, of course, that slow brain waves are made up of alternating phases of hyperpolarization and spike discharge, the latter appearing as a 'spike envelope'.

The hypothesis also explains other observations: (1) in the cat, the reduction in the duration of the short latency burst as the stimulus to the optic nerve is increased<sup>20,23</sup> could be due to the earlier onset or, more probably, the steeper rise of the summing IPSP's; (2) in the rat, the fact that the short latency response of the *P* cell is a single spike whereas later bursts contain 2-4 spikes could be due to the steeper onset of the first inhibitory phase; (3) in the rat, the existence of some 'labile' *P* cells which do not fire consistently at short latency even with stimuli

well above 'threshold', as well as *P* cells which do not fire early at all, for the same reason.

Finally, we now have extracellular and intracellular recordings from *P* cells showing summing IPSP's, the oscillations corresponding in number and frequency to the pattern of discharge of *I* cells. These findings will be reported in more detail later.

### Absence of Bile Acids in the Digestive Juice of the Swamp Crayfish (*Procambarus clarkii*)

ACCORDING to our present knowledge, bile salts are excreted in bile as the major metabolic product of cholesterol in vertebrates, whereas there has not yet been found any kind of steroid bile salt in invertebrates. Although Vonk<sup>1</sup> suggested that taurodeoxycholic acid might be present in the digestive juice of some crayfish, his experimental data were not entirely convincing.

Vonk's suggestion, if confirmed, would be of great interest for comparative biochemistry, and we have therefore examined it experimentally. The materials investigated were the digestive juice (*material I*) and the whole intestinal tract (*material II*) obtained from the swamp crayfish, *Procambarus clarkii*.

**Material I:** After each crayfish had been starved for 1 day, the digestive juice was sucked up from its stomach with a syringe and pooled in a vessel containing an aliquot of alcohol. The juice (20-30 ml.) obtained from 100 animals was worked up as one run. The alcoholic extract was hydrolysed (15 per cent w/v potassium hydroxide solution, 130° C, 3 h); and, after being freed from neutral lipids, it was extracted with ether after acidification.

The acidic fraction thus obtained was examined by our enzymatic method<sup>2</sup> using C-3-hydroxysteroid dehydrogenase<sup>3</sup>. Repeated experiments showed that the amount of NAD-reducing substance in each juice sample was only within experimental error.

**Material II:** Pieces (total wt., 3.22 g) of intestinal tract obtained from 50 crayfish were homogenized together with

their contents and extracted with methanol. After being freed from neutral lipids as usual, the acidified extract was extracted with butanol. This extract (*material II<sub>1</sub>*), after evaporation, was hydrolysed in the same way as *material I*, giving *material II<sub>2</sub>*.

One of us had already reported<sup>4</sup> that the digestive juice of swamp crayfish contains taurochenodeoxycholic acid instead of taurodeoxycholic acid, because the alcoholic extract of that juice showed an ultra-violet absorption maximum (at 308 m $\mu$ ) similar to that of chenodeoxycholic acid, when treated with concentrated sulphuric acid (Kazuno *et al.*<sup>5</sup>). This finding was definitely confirmed by our repeated experiments using both *materials I* and *II*. It is, therefore, certain that both samples contained the substance that Hozumi assumed to be taurochenodeoxycholic acid. *Material II<sub>2</sub>* (as acetyl methyl ester), however, showed a quite different curve from that of the diacetyl methyl ester of chenodeoxycholic acid when treated with 70 per cent sulphuric acid solution, as shown in Fig. 1. It must be noted here that *material II<sub>2</sub>*, even when not treated with sulphuric acid, showed a strong absorption maximum near 270 m $\mu$ .

Decisive evidence that the digestive juice does not contain any kind of common bile acid was given, not only by the aforementioned enzymatic determinations, but also by thin-layer chromatography and by gas chromatography.

As shown in Fig. 2 (a), the butanol extract of *material II<sub>1</sub>*, once purified by reversed phase chromatography, showed a single spot running at a different rate from taurochenodeoxycholic acid. This spot might correspond to that obtained by paper chromatography in our early experiments, which had been scarcely distinguished from the spot given by taurochenodeoxycholic acid. The

Fig. 1. The ultra-violet absorption curves of *material II<sub>2</sub>* (acetyl methyl ester) (A) and diacetyl methyl chenodeoxycholate (B). Above: treated with conc.  $H_2SO_4$ ; below: treated with 70 per cent w/v  $H_2SO_4$ : water

Fig. 2. a, Thin-layer chromatogram of *material II<sub>1</sub>* (A). Solvent system: ethyl acetate:glacial acetic acid:methanol (80:10:10, by vol.). b, Thin-layer chromatogram of *material II<sub>2</sub>* (B). B: methyl ester; C: acetyl methyl ester. Solvent system: benzene, ethyl acetate (40:60, by vol.). Standards for both chromatograms: glycochenodeoxycholic acid (1); glycocholic acid (2); taurochenodeoxycholic acid (3); taurocholic acid (4); methyl lithocholate (5)

acidic fraction obtained from the hydrolysate (*material II<sub>2</sub>*), and the acetyl methyl ester of this, however, showed unexpectedly 3 or 4 spots instead of a single spot on a thin-layer chromatogram; these spots were found to be quite different from the corresponding spot given by chenodeoxycholic acid and its esters (Fig. 2 (b)).

It must be noted that there was found, among these, a spot near that given by lithocholic acid acetyl methyl ester, but not near that given by diacetyl methyl chenodeoxycholate.

Since both the methyl ester and acetyl methyl ester of *material II<sub>2</sub>* had an aromatic odour, the latter ester was subjected to steam distillation. It was found that the non-distillable fraction showed a single spot on the chromatogram near the spot given by the acetyl methyl ester of lithocholic acid.

The foregoing fraction was further subjected to gas chromatography (type: Shimadzu A-2; column: 2 per cent SE-30, 2.5 m in length; temp. 215° C), in comparison with the acetyl methyl ester of lithocholic acid. The results indicated that this fraction was not a single material but developed at least three peaks, all having retention times much less than that of acetyl methyl lithocholate.

### An Action Spectrum for the Fire Ant (*Solenopsis saevissima*)

EVALUATION of the visual system of ants is important for a comparative analysis of photoreceptor processes in animals. The honeybees have been the subject of numerous visual studies, but ants have been virtually ignored. We have begun an extensive investigation into the spectral responses, eye structure, and visual pigments of ants, and here report our results on the action spectrum.

In previous attempts to obtain an action spectrum for ants, poorly controlled stimuli and filters with broad transmission bands precluded accurate measurements. However, ants were shown to react strongly to ultra-violet light and to be insensitive to red light<sup>1,2</sup>.

The ants used in the present study were from a laboratory colony of fire ants (*Solenopsis saevissima*), generously supplied by Dr. E. O. Wilson of Harvard University. After feeding in the same location for several days, with continuous illumination (control light) on one side of the nest, the ants learned to use the light as a source for orientation in the fashion of the Sun compass reaction. When the control light was turned off, then turned on again, foraging ants became alarmed and began running towards the nest. When the light was moved to the opposite side of the nest (stimulus light), the ants would reverse direction.

Although foragers following odour trails would reverse direction along the trail when the control light was changed directly to the stimulus light, so many of them became alarmed that the alarm response so evoked was more easily and accurately observed. All the alarmed foragers reversed direction when the stimulus light was the same intensity as the control light. As the intensity of the stimulus light was reduced, the percentage of ants reversing direction decreased. The intensity response curve illustrated in Fig. 1 was sigmoid, and the percentage of response was a nearly direct function of log intensity over the greater part of the curve.

For each monochromatic test light, the maximal intensity which produced just less than 10 per cent

Fig. 1

Fig. 2

positive responses, or fewer than 3 out of 25 ants reversing direction, was chosen as threshold.

The stimulus and control light were 60-W General Electric lamps encased in dark boxes with a 2.5-cm<sup>2</sup> opening. They were placed on opposite sides of the nest, which was on a glass platform covered with white paper. These were the only lights in a dark room except for a dim red overhead light.

The wave-length of the stimulus light was varied with combinations of Corning interference filters which pass relatively narrow bands of monochromatic light. Intensity was adjusted with Kodak neutral density filters. Determination of the dominant wave-length and calculation of the relative energies of the different monochromatic lights are discussed by Wolken *et al.*<sup>3,4</sup>.

Since the turning response is a clear and direct function of light intensity (see Fig. 1), we are justified in assuming that different response thresholds for various wave-lengths represent differences in physiological intensity.

Fig. 2 illustrates the action spectrum for the fire ant. The major response was found for ultra-violet light near 360 mμ. This confirms the results of earlier studies of ants and other insects, such as the honeybee, housefly and cockroach<sup>5</sup>. In the visible region of the spectrum, the response peak at 505 mμ is similar to the spectral sensitivity peak found in a wide variety of insects<sup>5,6</sup> and other animals. Sensitivity in this region of the visible spectrum has been associated with absorption characteristics of vertebrate rhodopsins.

While previous studies suggested that ants were not sensitive to red light, we found that the fire ant had an additional response peak near 620 mμ. In a study of colour preference of the odorous house ant, *Tapinoma sessile*, a similar response peak was found in the near red region. Such responses in the near red have been found in honeybees as well as in such lower invertebrates as protozoa and coelenterates. Whether this reflects receptor sensitivity or is due to decreased absorption at lower frequencies by the ommochromes or pigment granules that surround the retinula cells is not clear at present. Preliminary microspectrophotometric studies of the absorption spectra of

ommochromes suggest that they function as cut-off filters that pass some near-red but no other visible light.

The action spectrum must be distinguished from photoreceptor sensitivity. Response peaks cannot be directly equated with either receptor types or the absorption characteristics of the photosensitive eye pigment. However, the action spectrum seems to be a close reflexion of the summated sensitivity of all receptor types. Those wave-lengths where the response is greatest are the wave-lengths where the total sensitivity is greatest but not necessarily characteristic of the sensitivity peak of any one type of photoreceptor<sup>7</sup>.

## Acid Secretion and Electrogenesis in Isolated Rat Stomach

THE physiological aspects of acid secretion have been investigated for many years in the dog<sup>1</sup>, while Teorell's work in the cat has provided much information on the relation to CO<sub>2</sub> of various ions involved in secretion<sup>2</sup>. There have been extensive *in vitro* investigations of the transport mechanisms in frog tissue<sup>3</sup>, and it has been shown that electrical phenomena in these preparations are substantially dependent on chloride ions<sup>4,5</sup>. In contrast, more recent *in-vitro* experiments with rat tissue<sup>6</sup> show that gastric bioelectric activity depends on sodium ion movement. Because it was possible to characterize a sodium-dependent mechanism in the rat by substitution and ionic flux determinations<sup>7</sup>, we decided to investigate the relation between acid secretion and the sodium-specific transmural potential. The evidence, described here, suggests that changes in potential and in acid secretion are essentially independent of each other.

Electrical measurements were based on the method of Ussing and Zerahn<sup>8</sup>, using a chamber modified for rat stomach<sup>9</sup>. Acid or base formed by the stomach was directly titrated potentiometrically in the chamber, with simultaneous recording of the transmural potential. The titration end-point was a null electrometer reading between glass and calomel electrodes. Electrical balance was adjusted by means of a Zener stabilized power supply, a method shown by others to measure very small pH changes<sup>10</sup>. The medium was maintained at 34° C and at pH 6.3. Eighty ml. of a Krebs-Ringer type solution was added on each side of the tissue. The solution consisted of: 148 mM Na<sup>+</sup>, 5.6 mM K<sup>+</sup>, 1.4 mM Mg<sup>++</sup>, 3 mM Ca<sup>++</sup>, 157 mM Cl<sup>-</sup> and 7 mM glucose. The medium was gassed with pure oxygen. In the substitution

experiments, the appropriate ion was replaced by an osmotically equivalent amount of choline (for sodium) or sulphate (for chloride). Lactate was determined enzymatically<sup>11</sup>.

Fig. 1 compares both titratable acid and base production of rat stomach to the transmural potential of the unstimulated stomach. Both acid and base production continue to increase linearly with time, whereas potential rises to a peak at 60 min and declines thereafter. This indicates a difference in the source of the electrical and acid parameters. The average value obtained for acid secretion amounts to 10  $\mu$ equiv./h, a value similar in magnitude to that reported for the undisturbed rat stomach *in vivo*<sup>12</sup>. More recently, higher rates have been reported<sup>13</sup>, but the pH of titration was not stated. Since we observe markedly higher rates of acid secretion at pH 7.4 and greater, in part reflecting the titration of other groups as indicated by others<sup>14,15</sup>, no direct comparison can be made between these reports.

It is not surprising that base is formed on the serosa, since Davies and Longmuir<sup>16</sup> have shown that base is formed near the mucosa during acid secretion. That there is not a stoichiometric amount of base produced may be due to a limited diffusion of base through the muscular layers of the excised tissue, or to hindrance of base migration caused by the tying of part of the serosa on the lip of the holder. Furthermore, some of the base formed may be neutralized by lactic acid, which can amount to 20 per cent of the total titratable acid (Table 1).

Table 1. EFFECT OF SELECTIVE SUBSTITUTIONS AND HISTAMINE ON ACID SECRETION AND BIOELECTRIC POTENTIAL

Medium	n	Time <i>in vitro</i> of measurements (min)	Titrateable acid (mucosa) ( $\mu$ equiv./h)	Titrateable base (serosa) ( $\mu$ equiv./h)	Potential at 60 min (mV)
Krebs-Ringer (control)	8	30-90	9.8	4.7	19
Choline Ringer	4	30-90	10.4	5.3	-1
Sulphate Ringer	3	30-90	10.2	3.4	21
Krebs-Ringer + histamine $5 \times 10^{-4}$ M	4	60-120	13.3	7.0	*20
			Lactate ( $\mu$ equiv./h)	Lactate ( $\mu$ equiv./h)	
Krebs-Ringer	4	30-90	2.1	1.0	—

\* Value at 70 min, 10 min after addition of histamine; not significantly different from control.

Table 1 shows the effect on acid secretion of substituting choline for sodium. Potential can be eliminated by this substitution, as was demonstrated previously<sup>4</sup>, but the amount of acid or base formed is not affected (Table 1). This result indicates that the secretion of acid is not electrogenic in the sense of being directly related to potential. Substitution of sulphate for chloride did not affect the rate of acid secretion, although it did lower the rate of base formation. This may be due to a restriction of base migration across the tissue by decreasing exchange.

Fig. 1. Comparison of bioelectric potential with acid and base formation in rat stomach. Titration was performed directly in the chamber as described in text and potential was simultaneously recorded.

able chloride ion, as indicated by Teorell<sup>2</sup>. Durbin found that acid secretion is lowered in frog gastric mucosa in sulphate media<sup>17</sup>; it follows that frog tissue differs from rat tissue in the ionic requirements for acid secretion, as well as in transmural potential.

Histamine ( $5 \times 10^{-4}$  M) increases acid secretion from 10 to 13  $\mu$ equiv./h and base formation from 4 to 7  $\mu$ equiv./h (Table 1). Lower concentrations of histamine are less effective. In addition, the increment in acid secretion will vary from 0 to 6  $\mu$ equiv./h, an inconsistency also noted in frog<sup>18</sup>. Unlike frog, the degree of stimulation in rats is never dramatic, perhaps reflecting the continuous acid secretion in rat. Histamine does not affect the potential; therefore, acid production can be affected without changing the sodium-dependent electrogenic mechanism.

Most investigations on acid secretion *in vitro* have been performed on frog tissue, but the experiments described here show that acid and base production can easily be determined in the rat. Both chloride and bicarbonate have been eliminated from the medium without affecting mucosal acid production, and it appears that there is no inter-relationship between acid secretion and transmural potential. The results suggest that further work on hydrogen ion movement in rat tissue, in relation to the mechanism and control of acid secretion, may be profitable.

## Actinomycin D Inhibition of the Adaptation of Renal Glutamine-deaminating Enzymes in the Rat

PREVIOUS investigations have shown that metabolic acidosis leads to significant increases in the activities of glutaminase and glutamine transaminase- $\omega$ -amidase (GTA) in kidneys of rats<sup>1,2</sup> and guinea-pigs<sup>3</sup>. These changes are associated with, and thought to be related to, the adaptation of renal ammonia excretion to acidosis in the rat<sup>2,4</sup> and guinea-pig<sup>3</sup>. The response of renal glutaminase to metabolic acidosis is not mediated by the adrenal gland<sup>5</sup> or substrate, glutamine<sup>6</sup>, and is restricted to the kidneys<sup>6</sup>. Goldstein and Kensler<sup>5</sup> found that administration of ethionine to guinea-pigs inhibited the acid-induced rise in renal glutaminase activity, and we suggested that metabolic acidosis stimulates the synthesis of glutaminase by renal cells. The manner in which this stimulation occurs is unknown. Kroeger<sup>7</sup> has recently reported that alterations in the electrolyte balance of the medium bathing isolated salivary glands of the insect *Chironomus thummi* produced marked and specific changes in the gene activities

(RNA synthesis) of the giant chromosomes found in these glands. Metabolic acidosis and the accompanying changes in electrolyte balance might have similar effects on RNA synthesis in renal cells. Actinomycin D, an antibiotic which interferes with the DNA-dependent synthesis of RNA in bacterial and animal cells<sup>8</sup>, has been shown to inhibit the synthesis of RNA in rat kidneys<sup>9</sup>. The effects of this antibiotic on the responses of renal glutaminase, GTA and ammonia excretion to metabolic acidosis were therefore investigated in the rat.

Male Sprague-Dawley rats, 250–300 g, were kept in individual cages and maintained on Purina 'Lab Chow' and water *ad libitum*. The animals were divided into four experimental groups: (1) control rats injected with propylene glycol; (2) rats injected with actinomycin D; (3) acidotic rats injected with propylene glycol; (4) acidotic rats injected with actinomycin D. Rats were made acidotic by intragastric administration of 40 m.moles ammonium chloride/kg given in two equally divided doses over a period of 24 h. Actinomycin D (obtained from Dr. George E. Boxer, Merck, Sharp and Dohme Research Laboratories), 200  $\mu$ g/kg, was dissolved in 0.1 ml. propylene glycol and injected intraperitoneally in two equally divided doses at the same time that ammonium chloride was administered. All animals were in good condition at the end of the 24 h and the only significant changes observed were haemoconcentration and low rate of urine flow in group 4. Attempts to lengthen the experimental period to 48 h were unsuccessful, however, because of the high mortality rate in group 4 on the second day of treatment.

Rate of renal ammonia excretion was measured at the end of the 24-h period of treatment. Since urinary pH has a marked effect on renal ammonia excretion in the rat<sup>10</sup>, groups 1 and 2 were given 20 m.moles ammonium chloride in 20 ml. water/kg by stomach tube immediately before collection of urine in order to lower the pH of the urine of these two groups to the level of that observed in groups 3 and 4 (approximately pH 5.5). Groups 3 and 4 received an equal volume of water by stomach tube. The rats were then placed in metabolism cages and urine was collected for 4 h. Urine pH was measured by use of a Beckman 'Expanded Scale' pH meter and urinary ammonia concentration was determined by a microdiffusion-colorimetric technique<sup>5</sup>. Immediately after the period of urine collection, the rats were killed, and slices of renal cortex were removed and homogenized in 19 volumes of ice-cold water. The homogenate was centrifuged for 10 min at 500 g and 2° C to remove unbroken cells and nuclei. The supernatant fraction was removed from the precipitate and analysed for protein, glutaminase and GTA activities. Protein concentration was determined by use of the biuret reagent. Glutaminase activity was assayed by the procedure of Rector *et al.*<sup>4</sup> and GTA by the method of Goldstein *et al.*<sup>3</sup>

The results of these investigations are shown in Table 1. Metabolic acidosis produced a 55 per cent increase in renal cortical glutaminase activity and approximately an 80 per cent elevation in renal glutamine transaminase- $\omega$ -amidase activity within 24 h with no significant effect

Table 1. EFFECT OF ACTINOMYCIN D ON THE RESPONSES OF RENAL GLUTAMINASE AND GLUTAMINE TRANSAMINASE- $\omega$ -AMIDASE ACTIVITIES AND RENAL AMMONIA EXCRETION TO METABOLIC ACIDOSIS IN THE RAT

Group	Protein (mg/g cortex)	Glutaminase ( $\mu$ moles NH <sub>3</sub> /g protein min)	Glutamine transaminase- $\omega$ -amidase ( $\mu$ moles NH <sub>3</sub> /g protein min)	Ammonia excretion ( $\mu$ moles/100 g body-wt. h)
Control	170 $\pm$ 11	184 $\pm$ 27	17 $\pm$ 2	37 $\pm$ 4
Actinomycin	156 $\pm$ 7	173 $\pm$ 16	15 $\pm$ 1	27 $\pm$ 2
Acidosis	180 $\pm$ 9	287 $\pm$ 24*	31 $\pm$ 1†	58 $\pm$ 5*
Acidosis and actinomycin	180 $\pm$ 11	177 $\pm$ 12	21 $\pm$ 2	57 $\pm$ 7*

Values significantly different from control group are marked \* ( $P < 0.05$ ) or † ( $P < 0.01$ ).

Rats were made acidotic by intragastric administration of 40 m.moles ammonium chloride/kg in two equally divided doses over a 24-h period. Actinomycin D, 200  $\mu$ g/kg, was injected intraperitoneally in two equally divided doses at the same time that ammonium chloride was administered. Values are mean  $\pm$  S.E. of five rats per group.

on protein concentration. Administration of actinomycin D completely suppressed the acid-induced rise in renal glutaminase activity and produced a marked depression in the response of renal GTA activity. The antibiotic had no significant effect on basal protein concentration and enzyme activities (Table 1). The degree of acidosis was similar in rats receiving ammonium chloride plus actinomycin as compared with those receiving ammonium chloride alone, since the pH of the urine 20 h after administration of the final dose of ammonium chloride was  $5.5 \pm 0.1$  (mean  $\pm S.E.$ ) in the former group and  $5.7 \pm 0.1$  in the latter group. The inhibition of the adaptations of renal glutaminase and GTA by actinomycin appears, therefore, to be a specific effect of the antibiotic on the kidney. These results support the hypothesis that metabolic acidosis stimulates the production of specific ribonucleic acids by the renal cells which are involved in the synthesis of glutaminase and GTA. Other investigators<sup>11</sup> have shown that actinomycin blocks the glucocorticoid-induced rises in a number of hepatic enzymes, and Karlson<sup>12</sup> has suggested that some hormones may produce their effects by alteration of nuclear RNA synthesis. It may be that a number of general stimuli that have marked effects on cellular metabolism in higher organisms, such as hormones, diet and electrolyte balance<sup>13</sup>, exert their effects by means of the nucleus.

As shown in Table 1, metabolic acidosis produced approximately a 55 per cent increase in rate of renal ammonia excretion. Administration of actinomycin had a slight depressive effect on basal ammonia excretion but had no significant effect on the response of ammonia excretion to metabolic acidosis. The latter result was unexpected, since the rises in renal glutaminase and GTA activities, which are thought to play a part in the adaptation of renal ammonia excretion in the rat<sup>3,4</sup>, were suppressed by the antibiotic. These results indicate that adaptation of renal ammonia excretion can occur without a corresponding increase in activities of renal glutamine deaminating enzymes, but it is possible that actinomycin produced a secondary change(s) in acidotic rats that might have increased the rate of ammonia excretion. Two factors which might have been altered by actinomycin, blood ammonia and glutamine concentrations, were found to be similar in all four groups. In support of the theory that an increased production of urinary ammonia can occur during metabolic acidosis without changes in renal enzyme activities is the observation that the acid-induced adaptation of renal ammonia excretion observed in the dog<sup>14</sup> is unaccompanied by increases in renal glutaminase and GTA activities. It remains to be seen whether other examples of divergence between renal ammonia excretion and glutamine deaminating enzyme activities will be found in the rat.

## PHARMACOLOGY

### Significance of Worm Shifts in Experimental Schistosomiasis mansonii, with Emphasis on the Action of Anaesthetics

ALL schistosomicidal drugs eventually cause a change of location or 'shift' of the worms from the mesenteric veins, where they are normally found in infected animals, into the liver. There the parasites ultimately die and are ensheathed and phagocytosed by the protective mechanisms of the host. These worm migrations may be very rapid in onset and short in duration, as occurs with antimonials<sup>1</sup>; or they may be slow in onset and permanent in duration, as occurs with diphenoxylalkanes<sup>2</sup>. Various other schistosomicidal drugs produce 'hepatic shifts' with intermediate characteristics. The cause of the worm migrations differs with the different drugs, but essentially it results in paralysis of the worms which are thereafter swept back by the blood stream into the liver. Where the course of treatment is inadequate, the parasites regain their muscle control and return to the mesenteric veins.

It should be emphasized that whereas all schistosomicides sooner or later induce a hepatic shift, not all drugs that cause such a change of worm locality are of any use as schistosomicides. This paper deals with some drugs of this sort, which are pharmacologically active, yet of no clinical importance in schistosomiasis. Of these, perhaps the most worthy of mention is the group of general anaesthetics.

Table 1. EFFECT OF ETHER ON WORM DISTRIBUTION

	Av. No. worms/mouse	Per cent distribution in:		
		Mesenteric veins	Portal vein	Liver
Autopsy after killing with ether	11	0	6	94
Recovery after anaesthesia:				
0.5 h	11	0	7	93
2 h	11	59	20	21
Control	12	76	16	8

When ether is administered to mice infected with *S. mansonii*, a major shift of the worms from the mesenteric veins into the liver occurs more or less immediately as anaesthesia sets in (Table 1). The 'hepatic shift' lasts as long as the anaesthesia itself, and if the animal is allowed to recover, the parasites slowly migrate back. If anaesthesia is taken to a lethal level, a 100 per cent shift of the worms is seen at autopsy. These observations hold true for other inhalation anaesthetics, for example chloroform, as well as for the group of barbiturate drugs.

The mechanism of action of these drugs in inducing this worm behaviour is uncertain, but it could be due to a depressant action on the central ganglion of the parasite. In experimental schistosomiasis some earlier workers<sup>3,4</sup> killed their animals for autopsy using ether or chloroform, a procedure which must have undoubtedly compromised their results with regard to the worm distribution after drug treatment.

The clinical significance of this action of anaesthetics and central depressants should not be neglected. Bilharzial patients are apt to take these or other pharmacologically active drugs during everyday life; such drugs may keep the worms going to and fro in the hepatic portal system with possible undesirable complications. Portal block, which may have serious consequences, may follow the use of such drugs in heavily infected patients.

Testing a new drug for anti-schistosomal activity in experimental animals will invariably involve observation of worm distribution within the hepatic portal system after treatment. In such investigations the test animals should always be killed by cervical dislocation, or by some means other than anaesthesia. If the use of the latter is unavoidable, then its effects should be taken into consideration, not neglecting the fact that, although the worm shift to the liver is indicative of an action on the parasites, it is not necessarily evidence of schistosomicidal properties.

## HAEMATOLOGY

### Two Populations of Platelets

It has been suggested that the tail frequently observed in a platelet survival study could be explained by a young population of platelets having a longer life span than the remainder<sup>1</sup>. The following experiments demonstrated the presence of two morphologically different populations, following the exposure of human platelets to osmotic stress.

Platelets were obtained from whole blood collected in 2 per cent ethylenediamine tetraacetic acid (EDTA) by differential centrifugation and then centrifuged at 2,000 r.p.m. for 10 min; after removal of the plasma the platelets were re-suspended in 0.85 per cent NaCl and re-centrifuged.

The platelets were then equally divided; one half was placed in distilled water and the other in 0.85 per cent NaCl to act as a control. At various intervals ranging from 10 sec to 1 h, samples were taken from both and, in the case of the distilled water treatment, were added to an equal volume of 1.8 per cent NaCl to make the samples isotonic. The platelets were then centrifuged and fixed as a pellet in 1 per cent osmium tetroxide in Palade's buffer for 1 h. After dehydration through graded alcohols they were embedded in 'Araldite' and sections were cut on an L.K.B. 'Ultratome'. A Philips *E.M.* 200 electron microscope was used to examine the sections.

Fig. 1 shows the changes present in the platelets after 10 min in distilled water. It can be seen that they behaved in one of two ways: either they appeared pale, round and slightly expanded, frequently showing breaks in the cell membrane with an apparent loss of cytoplasmic organelles; or they became darker and slightly contracted, having a continuous cell membrane with many pseudopodia and the usual cytoplasmic organelles. The paler group of platelets became evident after 10 sec in water and the darker group after 60 sec. By 10 min no 'normal'

platelets remained and the two distinct groups were clearly evident. No further morphological change could be noted at 30 and 60 min. Similarly, two types of platelets have been observed in a preliminary study using hypertonic saline.

Serial sectioning was performed to prove that two distinct platelet populations were present. It seems likely that these changes may correspond to the 'spread' and 'sword' forms seen in whole platelets subjected to hypotonic solutions in studies of osmotic fragility<sup>2,3</sup>.

The difference in response to hypotonicity that we have observed probably reflects biochemical differences in the platelet population. This may be due to (i) platelet age, (ii) two biochemically distinct but normally morphologically similar groups of platelets, or (iii) artefact induced in handling. The possibility of an artefact, however, is unlikely, as one patient with severe thrombocytopenia showed only one type of platelet, the 'paler' type, when tested in this way. Further studies are being undertaken in an attempt to determine whether or not these changes are due to age. The possibility that there are two platelet populations has obvious importance in studies of platelet physiology and pathology.

### Efficiency of Searching Gm Antigens for Identification of Blood-stains in Forensic Medicine

THE recent communications of Brocteur and Moureau<sup>1</sup>, and Nielsen and Henningsen<sup>2</sup>, as well as the interest found in seric groups, lead us to report here a forensic investigation illustrating the importance of the Gm antigens for identification of blood-stains.

In September 1961, a suitcase containing a sum of money was stolen, and it was recovered on waste ground; its lid had been cut, probably with a sharp knife. A thorough examination revealed two very small brown-red stains, looking like blood, on the lid. A suspect arrested soon afterwards had a wound on his thigh, and his trousers were torn at the very spot where the knife must have wounded him.

The police reconstructed the facts as follows: the man had stolen the suitcase, had put it on his lap and, trying to cut it open with his knife, had implanted the blade in his thigh. To verify this hypothesis, we had to prove that the brown stains on the suitcase could have come from the man's blood and that they were similar to the blood-stains found on the trousers.

The difficulty in this investigation was that the stains were very small, making it impossible to determine the antigens of the ABO system or, of course, those of the P or Rh systems. So, after having shown the presence of peroxidase and human proteins in these stains, we tried to identify them simply by searching Gm (a) and Gm (x) antigens.

In fact, the subject was A<sub>1</sub> Rh + Gm (a + x -). Because of the lack of specificity of some anti-Gm (b) sera, we had refrained from using this system in a forensic investigation.

Fig. 1. Platelets after 10 min in distilled water

Table 1

	Anti-Gm (a)						Anti-Gm (x)					
	1/1	1/2	1/4	1/8	1/16	1/32	1/1	1/2	1/4	1/8	1/16	1/32
Stain Gm (a+ x+)	—	—	—	—	—	—	—	—	—	—	—	—
Stain Gm (a- x-)	+++	+++	+++	++	+	—	+++	+++	++	+	—	—
Blood-stain from trousers	—	—	—	—	—	—	—	—	—	—	—	—
Unstained cloth from trousers	+++	+++	++	+	(+)	—	+++	++	+	(+)	—	—
Blood-stain from suitcase	—	—	—	—	—	—	+++	++	+	(+)	—	—

A maceration was prepared by scraping the stains with a bistoury blade and then dissolving the particles thus obtained in physiological serum. This maceration was then brought into contact with anti-Gm (a) serum in one tube, and with anti-Gm (x) in another tube. After incubation for 2 h at laboratory temperature, the titration of the anti-Gm (a) sera was determined by the usual techniques. At the same time, similar preparations were carried out on the trousers stains and on the controlling blood-stains. Table 1 shows the precision of the results obtained which permitted us to say that the stains found on the suitcase might well have come from the suspect's blood. So far as we know, this is the first forensic investigation which has been conducted with the Gm antigens in blood-stain identification.

Since then, we have carried out several investigations to assess the place of Gm antigen determinations in blood-stain identification<sup>3-5</sup>.

The Gm antigens are particularly useful for minute blood-stains<sup>6</sup> because they are often the only antigens that can be used, at least when the absorption techniques are preferred. This kind of investigation can always be relied on: the absorption is always total, even when the stain is very old; we have thus been able to determine the Gm phenotype of experimental stains made 10 years ago.

## HISTOLOGY

### Autofluorescence of Eosinophils: a Bone Marrow Study

DURING a fluorescent immuno-histological investigation of bone marrow, we observed that certain granulocytes of the unaltered control series showed intense yellow autofluorescence of their granules instead of the expected light yellow-green autofluorescence of cytoplasm<sup>1</sup>. These cells were identified as eosinophils by Wright's stain and phase contrast microscopy. We considered this finding an original observation until we recently found a previous reference<sup>2</sup>. Our report is intended to confirm the reference and quantitate the autofluorescence with reference to individual patients.

Bone marrow smears from sternal aspirations of twenty unselected patients were immediately fixed in 95 per cent alcohol and stored at room temperature. Preliminary work indicated that the alcohol had no effect on the autofluorescence. The slides were mounted with glass coverslips and low-fluorescent buffered (pH 7.2) glycerine. The total white blood cell counts, with two exceptions (chronic lymphatic leukaemia), were within the normal

range. Eosinophilia (10-20 eosinophils per 100 white blood cells) was present in the two cases of intestinal parasitism. The patients were receiving a variety of medications. A Leitz 'Ortholux' microscope with combined tungsten and ultra-violet light (Osram 'HB' 200 W) was used with a monocular photo-tube. Although several combinations of the commonly used exciter and barrier filters produced strong fluorescence of the granules, we used the BG12 exciter filter and the Blau Absorbing (OG1) barrier filter for the entire study. With this system the autofluorescence of the eosinophilic granules was an intense yellow. The cytoplasm of neutrophils often produced a faint yellow-green autofluorescence. A dark field, variable phase, or bright field condenser was used when indicated with the appropriate objectives. Photographs were taken with a Mikas attachment and a 35 mm Leica camera back using Kodak 'Pan X' film. Each eosinophil was first identified under dark field examination by its coarse granules which often produced a white glow; then under ultra-violet light the amount of fluorescence was graded zero to four plus. A cell was graded as one plus when the autofluorescence enabled the granules of the eosinophil to be identified from the background fluorescence, and as four plus when a very intense fluorescence produced a glow beyond the edge of the granule (Fig. 1). The grades two plus and three plus were arbitrary intermediate levels. Twenty eosinophils were identified and graded on each smear of bone marrow. The dark field identification was checked by maintaining the eosinophil in position and changing to phase-contrast microscopy.

Significant autofluorescence of the eosinophilic granules was noted in most preparations. The great majority of eosinophils in each slide showed autofluorescence. (Average 97.5 per cent, range 75-100 per cent.) There was surprisingly little variation of intensity within each preparation,

Fig. 1. Two eosinophils with intense yellow autofluorescence of the granules. Other cells of the granulocytic series show a very slight yellow-green autofluorescence of the cytoplasm ( $\times 1,000$ )

most of the eosinophils from each patient showing the same level of autofluorescence. Table 1 illustrates the autofluorescence according to principal diagnosis.

Although the eosinophil has been the subject of countless investigations, its remarkable autofluorescence in the range of the commonly used fluorescent microscopy systems has received scant attention. This study confirmed the previous report in which Grossi and Zaccheo described the autofluorescence of eosinophilic granules but made no comparisons between individuals. Our attempts to quantitate the autofluorescence revealed marked individual differences but apparently no relation to principal diagnosis (Table 1). We also found that no correlation was

Table 1. AUTOFLUORESCENCE OF EOSINOPHILS FROM 20 PATIENTS ACCORDING TO PRINCIPAL DIAGNOSIS

\* Variation occurred in the eosinophils of three patients with iron deficiency anaemia.

possible between the drug therapy and the intensity of autofluorescence. A correlation may exist in the case of certain drugs, but a much larger series of well-controlled data would be necessary to reveal it. Many organic chemicals are fluorescent within the range of the equipment used in this study and many factors are probably important in producing the autofluorescence of eosinophilic granules demonstrated in this report. The phenomenon certainly warrants further investigation, but it is proper to direct attention to the need for caution in interpreting results of fluorescent staining techniques applied to bone marrow. Changes in pH, temperature, viscosity, ionic strength, heavy metals, and fixation can either increase or decrease fluorescence emission, and these factors must be meticulously controlled in all experiments. In the case of eosinophils the added factor of remarkable autofluorescence must also be carefully considered.

### Mast Cells of the Pituitary Gland

THERE is a marked similarity in the morphological appearance of mast cells and the parenchymatous glandular cells of the infundibular process (neural lobe) of the pituitary gland described by Gersh<sup>1</sup>. It has been suggested by Rennels and Drager<sup>2</sup> that the parenchymatous glandular cells may play a part in the final release of the hormones of the posterior pituitary into the general circulation. Although Gray<sup>3</sup> described mast cells in the pituitary gland of man, ox and cat, the presence of these cells seems to have been largely ignored by more recent workers.

In the present investigation an attempt has been made not only to identify mast cells in a variety of mammalian pituitary glands, but also to determine their relationship to the parenchymatous glandular cells.

The pituitary glands of man, bullock, calf, rat and mouse were investigated. Of a variety of fixatives employed, formol-Zenker gave the clearest detail. Mast cells were identified following staining with 2 per cent new methylene blue in 0.5 per cent lithium carbonate or

with 1 per cent toluidine blue at pH 3. For the identification of the parenchymatous glandular cells the method described by Gersh<sup>1</sup> was used. For each specimen examined, control tissues, known to contain mast cells, were removed and processed with the glands. These controls were mounted on the same slides as the pituitary sections. In this way identical control staining was obtained.

**Mast cells.** These were present in great number in the infundibular process of the bullock and the calf; as many as 150 per low power field were seen. A few were found in the pars intermedia and occasional ones in the pars distalis. The infundibular stem of the bullock was particularly rich in mast cells and they could be traced proximally to the region of the para-ventricular and supra-optic nuclei of the hypothalamus. More were found in the para-ventricular than in the supra-optic nucleus. None was found in sections of brain taken from a variety of sites other than the hypothalamus. Only occasional mast cells were observed in the pituitary gland of the rat, and many sections were completely devoid of them. Although an occasional mast cell has been seen in the capsule of the pituitary gland in the mouse, none was found in the parenchyma of the gland. In the human the mast cell population was variable. Occasional mast cells were found in the pars intermedia and pars distalis in all glands examined. In the infundibular process of one gland many mast cells were present, but in another no mast cells were seen. The distribution in the remaining glands examined lay between these extremes.

**Parenchymatous glandular cells.** In the pituitary gland of the rat and the mouse typical parenchymatous glandular cells were observed in all the sections examined. The mast cells in the control tissues failed to reduce osmic acid and could not be positively localized by this method alone. In the human, bullock and calf, no cells containing the typical black granules found in the rat and mouse were seen in the infundibular process, nor were these cells found in the control tissues. Cells containing refractile granules were seen, but they were identified as mast cells when stained with new methylene blue.

It is known that the mast cell distribution in the tissues varies from species to species, and the present findings indicate that this is true of the pituitary gland. The pronounced variation in the mast cell population of the human pituitary gland may be related to the physiological state of the body at the time of death. Variation with age cannot be a factor in the present survey, for all human glands examined were removed from cadavers of the same age group.

While it is possible to differentiate the parenchymatous glandular cells of the pituitary from mast cells in the rat and mouse, this is not the case in the human, bullock or calf. In these it is apparent that the cells described by Gersh<sup>1</sup> which contained refractile granules that did not reduce osmic acid are, in fact, mast cells.

### RADIOBIOLOGY

#### Dependence of DNA Synthesis on Irradiation Dose Rate

THE following report of work on the relationship of dose-rate depression of DNA synthesis is part of a more comprehensive investigation of the effects of irradiation on the biosynthetic mechanism of DNA replication. One of the specific reasons for the investigation was to determine whether one of the major criteria (dose-rate independence)

for utilization of the target theory was fulfilled for radiation effects of DNA synthesis in the biological test system used<sup>1,2</sup>.

Lewis strain rats (200 g) were used in these experiments. The irradiation was given using a 200-kVp. X-ray machine of half value layer, 1 mm copper. A 3-cm cone was used to deliver the irradiation locally to the liver. The experiments were designed so that all periods of radiation, with variations in dose rate, ended at 19 h after partial hepatectomy. The time, 19 h after partial hepatectomy, was chosen because it was previously found to be near the mid-point of the 8-h period of DNA replication in the rat hepatocyte. A total dose of 1,500 r. was used at dose rates of 300 r./min, 50 r./min, 25 r./min and 12.5 r./min. The fractionated dose-rate experiments were as follows: 500 r. at 17, 18 and 19 h after partial hepatectomy, and 750 r. at 17 and 19 h after partial hepatectomy. The total dose and dose rates were a compromise between the sensitivity of the detecting methods of DNA depression, the range of dose rates feasible, and the fraction of time of the DNA synthetic period over which the animals were irradiated.

50  $\mu$ c. tritiated thymidine, 3 c./mM mole, were given at the end of the period of irradiation. The animals were killed 1 h later and squashes made from random samples of finely minced liver. These were fixed by freeze substitution before the application of Kodak 'AR-10' stripping film.

Anaesthesia was necessary in order to keep the animals stationary during the varying periods of irradiation. Four groups of animals were anaesthetized with ether for the same periods used at the four different dose rates. These results are given in Table 1. No significant differences were found in the relative rates of DNA synthesis at 5, 30, 60 or 120 min of ether anaesthesia.

Table 1. THE EFFECT OF VARYING TIMES OF ETHER ANAESTHESIA ON DNA SYNTHESIS

Duration of ether	5 min	30 min	60 min	120 min
Mean grain counts per nucleus	32.4	32.8	26.4	26.7
S.E.	$\pm 7.5$	$\pm 7.9$	$\pm 5.5$	$\pm 2.1$
No. animals	6	5	6	11

Table 2. THE EFFECT OF VARYING IRRADIATION DOSE RATE ON THE DEPRESSION OF DNA SYNTHESIS (TOTAL DOSE 1,500 R.)

Dose rate	300 r./min	50 r./min	25 r./min	12.5 r./min	Controls
Time of delivery	5 min	30 min	60 min	120 min	
Mean grain counts per nucleus	25.1	19.5	15.6	9.7	37.7
S.E.	$\pm 2.2$	$\pm 1.5$	$\pm 1.3$	$\pm 1.4$	$\pm 1.8$
No. animals	10	8	7	7	41

Table 3. THE EFFECT OF DOSE FRACTIONATION GIVEN AT THE RATE OF 300 R./MIN ON THE DEPRESSION OF DNA SYNTHESIS (TOTAL DOSE 1,500 R.)

Dose fractionation	1,500 r. at 19 h after partial hepatectomy	750 r. at 17 and 19 h after partial hepatectomy	500 r. at 17, 18 and 19 h after partial hepatectomy
Mean grain counts per nucleus	25.1	21.5	28.8
S.E.	$\pm 2.2$	$\pm 4.3$	$\pm 3.7$
No. animals	10	6	5

The depression of DNA synthesis at the different dose rates is given in Table 2. The 1,500 r., given at the rate of 300 r./min, reduced the rate of DNA synthesis to approximately two-thirds of the control values. There is a consistent depression of the rate of DNA synthesis with the lowering of dose-rate and the increasing time of radiation. This becomes significant at the 0.05 per cent level when the rate of 2.5 r./min is reached (Fig. 1).

There was no significant difference in the depression of DNA synthesis if the total dose of 1,500 r. was given in 5 min, or in fractionated doses of 500 r. and 750 r. over a 2 h period (Table 3). This would suggest that the intensity of radiation given at a dose rate of 300 r./min is in excess of that needed to provide the optimum depression of DNA synthesis. The continuous depression of DNA synthesis with decreasing dose rates indicates that the optimum dose rate for depression of DNA synthesis has not been reached at 12.5 r./min.

Beltz, Van Lancker and Van Potter<sup>3</sup> found that decreasing the dose rate caused less depression of DNA synthesis rather than greater depression. They found

Fig. 1. Relation of radiation dose rate to the depression of DNA synthesis (total dose 1,500 r.)

that a dose rate of 10 r./min gave a concentration of  $2,156 \pm 462$  c.p.m./mg DNA, 19 r./min gave  $1,300 \pm 334$  c.p.m./mg DNA, and 39.5 r./min gave  $463 \pm 209$  c.p.m./mg DNA. Whole-body irradiation was used rather than local irradiation of the liver. The irradiation was started 24 h after partial hepatectomy. Orotic acid-6-<sup>14</sup>C was given 30 h after partial hepatectomy and the animal was killed 36 h after partial hepatectomy. The fact that the findings of Beltz *et al.* are contrary to the results presented here is, in all probability, due to the differences in the time of irradiation, injection of labelled precursors of DNA, and killing of the animal. The possibility that whole-body irradiation resulted in a greater depression at a higher dose rate from the indirect effects of irradiation seems less likely. Irradiation 24 h after partial hepatectomy would be irradiating the last part of the first cycle of hepatocytes synthesizing DNA, as well as the beginning of the second cycle of hepatocytes. Injection of orotic acid 30 h after partial hepatectomy would, in all probability, be taken up by the second cycle of hepatocytes in the controls and a mixture of first- and second-cycle hepatocytes in the irradiated animals. Differences in the time sequences in the irradiated and control animals could therefore lead to differences in the rate of uptake of labelled orotic acid.

The more probable explanation is that radiation affects one or more rate-limiting processes in such a way that the higher dose rate provides an excessive number of ionizing events per unit of time. If this were true, then the lower dose rate would be more efficient in producing the ultimate depression of DNA synthesis. This preliminary finding might be interpreted as follows: the rate of formation of the radiation-sensitive biological units is small, so that only a small number of ionizing events are needed to inactivate them. The results of the investigations of fractionated doses would suggest that effects, if any, on the formation of new biological units are of short duration, since the depression of DNA synthesis is essentially the same, whether the dose is given in 5 min, or given in divided doses over a 60- or 120-min period. Further investigations are in progress to elucidate the relation

ship between the rate of delivery of the radiation dose and the rate of depression of DNA synthesis.

This work was supported in part by Atomic Energy Commission contract AT(40-1) 2889, American Cancer Society grant E309 and U.S. Public Health Service grant GM10754-01.

## BIOLOGY

### Distribution of Indolyl-3-acetic Acid labelled with Carbon-14 in *Avena*

THE active transport of hormones in plants has been under investigation for a number of years. Speeds of transport have been reported in the literature, but there does not appear to have been any attempt to observe experimentally whether a well-defined front exists for the moving hormone stream. This lack of experiment is surprising since, as Canny<sup>1</sup> has pointed out, a speed of transport of a substance in a plant can only be simply defined if there exists a definite front to the stream of that substance. Such a front does not exist for translocated photosynthate nor would it be expected for hormone transport if the movement of the hormone were a diffusion-like process. Goldsmith and Thimann<sup>2</sup> find an exponential profile of a hormone in a section of *Avena* through which it had been passing for several hours. They assumed from this that no definite front exists and therefore they did not attempt an accurate measurement of transport speed.

From electric measurements on the *Avena* coleoptile Newman<sup>3,4</sup> has suggested that there is a definite front to the stream of indolyl-3-acetic acid (IAA) moving down a decapitated coleoptile from an IAA-agar block applied at the top. The basis of this suggestion was the observation that IAA induced an electric wave to move down the coleoptile at a constant speed and with little dispersion.

This communication describes an experiment in which the profile of the moving IAA in the *Avena* coleoptile was determined by application of radioactively labelled hormone to the cut top. It will be seen here that the results confirm the existence of a sharp front to the IAA stream. It is hoped that these results may assist in the development of a more complete description of the distribution and transport of IAA in the *Avena* coleoptile.

Oat seedlings were grown and prepared as previously described<sup>4</sup>. The experiment was performed under weak green light in a room kept at 25° C and 90 per cent humidity. Agar blocks of 5 mm<sup>3</sup> volume containing <sup>14</sup>C-carboxyl-labelled IAA (activity: 96 µc./mg) at a concentration of 0.03 ± 0.01 mg/l. were placed on the cut tops of the coleoptiles and renewed at 10-min intervals to ensure that a constant concentration of IAA was in contact with the top of each coleoptile. After 32 or 64 min the coleoptiles were cut into a number of 1 mm-long sections. All the sections from a particular level in the coleoptiles were placed upright on a small piece of agar for 7 min. During this time most of the moving component of the radioactive IAA in the sections moved into the agar block. No attempt was made to estimate how much of the hormone had become in any way bound in the tissue or how much unlabelled IAA may have moved in the stream. This may be the subject of further experiment. The agar blocks in which the transported IAA had been collected from the 1-mm sections were melted and spread over the surfaces of planchets to reduce self-absorption. They

Fig. 1. Counts per min against distance in millimetres below the cut top of the coleoptiles. ● 32-min experiment; ○ 64-min experiment. 95 per cent confidence limits of the measured count rates are shown for 3 positions on each graph

were dried and counted using a thin end-window Geiger-Müller counter with an anti-coincidence array which reduced the background to 1.6 c.p.m.

Fig. 1 shows the activity (c/min, corrected for background) of the hormone that diffused out of the sample of sections at each level in the 7-min period. This is plotted against the distance of the base end of each 1-mm section from the point of application of the hormone. The sample sizes were 11 coleoptiles for the 32-min experiment and 18 coleoptiles for the 64-min experiment.

Two clear deductions (valid for the concentration of IAA used) can be made from the results: the first is that, at a chosen time after application of the hormone, its concentration in the stream moving down the coleoptile falls approximately linearly with distance below the top. It is estimated that in each case the average IAA-<sup>14</sup>C concentration moving in the tissue 1 mm below the top is about 0.01 mg/l.; that is, about 1/3 the applied concentration. However, for the two results it is not useful to compare the intersection points of the lines with the activity axis since the concentration of IAA applied in the two cases was only fixed to within 30 per cent of 0.03 mg/l.

At a certain distance from the top the activity reaches zero or sharply levels off to a small positive value. This greater-than-background activity could have been caused by some contamination during the experiment or perhaps caused by a very small quantity of the hormone being transported much faster. Further experiment should elucidate this. In any event, the concentration of IAA detected in this region is less than 0.001 mg/l. and is probably physiologically insignificant. The second deduction from the results is then that the abrupt change of slope of the line shown in Fig. 1 for each time may reasonably be taken to define the position of the front of the IAA stream at that time. This front moves from 6.2 mm at 32 min to 12.0 mm at 64 min. The average speed of movement is therefore 11 mm/h. This is the same as the speed at which an electric wave has been observed to move down the *Avena* coleoptile under the same experimental conditions<sup>4</sup>, thus confirming that the electric wave is associated with IAA transport.

The results described show, therefore, that IAA, when applied to the top at a concentration of 0.03 mg/l., moves down the *Avena* coleoptile in a stream with a nearly linear profile. The front of this stream advances at 11 mm/h. The results are now being extended to other concentrations and other transport times.

I thank Dr. B. B. Stowe of Yale University for a gift of IAA-<sup>14</sup>C.

### *In vitro* Production of Neomorphs in *Anethum graveolens* L.

IN an earlier communication Johri and Sehgal<sup>1</sup> reported the chemical induction of polyembryony in *Anethum graveolens*. The work recorded here is an extension of that investigation.

In Nature the fruits mature approximately 25 days after pollination and the seeds show a copious fatty endosperm and a single minute embryo.

Young ovaries, three days after pollination (Fig. 1), were grown under aseptic conditions on a modified White's medium containing 4 per cent sucrose. This would be referred to as the basal medium. Casein hydrolysate, yeast extract and indolyl-3-acetic acid were used as supplements.

At the time of inoculation the ovules showed the zygote and a free nuclear endosperm. The ovaries implanted on basal medium and basal medium + indolyl-3-acetic acid

(1, 5, 10 p.p.m.) produced only monoembryonate seeds, while basal medium + casein hydrolysate (100, 1,000 p.p.m.) and basal medium + yeast extract (100, 1,000 p.p.m.)—with or without the addition of indolyl-3-acetic acid (1 p.p.m.)—induced polyembryony in 6–20 per cent cultured ovaries. In 13- to 14-week-old cultures the seeds germinated *in situ* and gave rise to normal seedlings. However, in a few cultures grown on basal medium + casein hydrolysate or basal medium + yeast extract, with or without indolyl-3-acetic acid, the seedlings were chlorotic and fasciated. Eight to 12 months later (cultures transferred through 4–6 passages of 8 weeks each) the fasciated tissues differentiated into embryo-like structures (Figs. 2 and 3) which finally developed into 1–2-cm-long thalloid (Fig. 4) or coralloid (Fig. 5) seedlings. These vegetatively reproducing plantlets, termed neomorphs, resemble the cotyledonary stage of a normal seedling. Further proliferation and multiplication of the neomorphs occurred in cultures maintained for 10–12 months (Figs. 3–5). On sub-culturing in basal medium, basal medium + casein hydrolysate or basal medium + yeast extract (with or without indolyl-3-acetic acid) for 6–8 weeks, they produced normal seedlings.

Earlier, Waris<sup>2,3</sup> reported that the mature seeds of umbellifers like *Cicuta virosa*, *Daucus carota*, *Oenanthe equatica* and *O. lachenalii* grown on a liquid medium (for detailed composition of this medium see ref. 3) containing 1 per cent sucrose and 0.1–0.4 per cent glycine produced more or less similar neomorphs. Miettinen and Waris<sup>4</sup> noted that the neomorphs contained a low concentration of sugars but had free amino-acids in a 10-times higher concentration than normal individuals. They therefore concluded that the accumulation of soluble amino-acids in the neomorphs indicated a disturbance in protein synthesis. They further suggested that the neomorphic condition of seedlings is a physiological adaptation to a higher concentration of glycine and does not involve any irreversible change of genotype.

It is possible that in *Anethum graveolens* also the amino-acids present in casein hydrolysate and yeast extract accumulate in the seedlings which produce the neomorphs, but this has to be confirmed by chemical analysis. In any case, like the induction of zygotic polyembryony, the production of neomorphs can be exploited by plant breeders for raising a large population of seedlings with desired characters.

We are grateful to Prof. P. Maheshwari for his keen interest in the progress of this work.

### Giant Chromocentres and Nucleoli in *Lumbricus*

FURTHER observations on intranuclear aspects of giant nuclei found in the pharyngeal epithelium in *Lumbricus* have been made. A previous report was given concerning these nuclei<sup>1</sup>. Not only were the overall dimensions of these nuclei enlarged when compared with the more typical nuclei, but also on examination of the intranuclear morphology it became apparent that giant chromocentres (Figs. 1, 4 and 6), giant nucleoli (Figs. 1, 2, 3, 4, 5 and 6), and even giant nucleolar organizers (Figs. 3 and 4) were present.

Endopolyploidy could explain these features if it were assumed that not only nucleolar fusion exists but also

chromocentre fusion. In *Drosophila* such fusion occurs with heterochromatic portions of the giant polytene chromosomes of the salivary gland. Large nucleoli and 'coarse-chromatin' (large chromocentres?) are terms commonly used in the description of nuclei of various neoplastic cells. In this respect it is of interest that giant nuclei of the same description presented in the previous report<sup>1</sup> have been given for nuclei in a pharyngeal tumour in *Lumbricus* by Stolk<sup>2</sup>.

Synthetic capacities and other functional qualities attributable to nucleolar organizers, and possibly chromocentres in general, may be greatly altered by a fusion process. These nuclear components because of their increased size should lend themselves admirably to autoradiographic experiments, designed to ascertain biochemical aspects of heterochromatin and nucleoli.

### Deoxyribonucleic Acids of Sperm, Eggs and Somatic Cells of the Sea Urchin, *Arbacia punctulata*

A SEARCH of the literature reveals no report of the comparative base composition of deoxyribonucleic acids isolated from the two gametes and the somatic cells of the same species. Yet the molecular events whereby genetic information from egg and sperm is integrated on fertilization are of fundamental importance in our understanding of the molecular basis of heredity and development in higher animals. These facts prompted the work recorded here, which is concerned with properties of the DNA isolated from sperm, eggs and adult somatic cells of the sea urchin *Arbacia punctulata*. Sperm and eggs were obtained either by the mild electric shock technique of Harvey<sup>1</sup> or by the injection of 0.5 M KCl<sup>2</sup> into the perivisceral cavity of adult sea urchins. The diploid tissues were obtained from spent adults, the gonads of which were discarded. The DNA from sperm and diploid tissues was isolated by a modification of the procedure described by Marmur<sup>3</sup>. High-molecular-weight DNA from eggs could not be prepared in this way unless the nuclei were first isolated by the method of Went and Mazia<sup>4</sup>. The hot phenol method<sup>5</sup> was also effective in the isolation of DNA from whole eggs. Failure to isolate egg DNA by mild procedures might be due to the presence of potent deoxyribonucleases, which in turn could account for the inability of some investigators<sup>6</sup> to obtain highly polymeric DNA from this source.

The buoyant densities in caesium chloride of the DNA preparations before and after heating in a boiling water bath, followed by quick chilling, are shown in Table 1 and Figs. 1 and 2. It is known that heating and quick chilling of double-stranded DNA molecules renders them single-stranded<sup>7</sup>. This is accompanied by an increase in

Fig. 4

Fig. 5

Sperm, prep. II†	1.700	41	Double-stranded
Sperm, heated	1.714	—	
Eggs, prep. IV‡	1.700	41	Double-stranded
Eggs, prep. V§	1.700	41	
Eggs, heated	1.714	—	

\* The guanine-cytosine contents were estimated from the buoyant densities on the assumption that the DNA contained no unusual bases or substituents. A previously described relationship was used (ref. 8).

† Prepared by a detergent procedure (ref. 3).

‡ Eggs pre-treated with dithiodiglycolate, versene and dextrose (ref. 4).

§ Prepared by a hot phenol procedure (ref. 5).

buoyant density of approximately 0.015 g/cm<sup>3</sup>. It can thus be seen that the deoxyribonucleic acids isolated from both eggs and sperm are double-stranded and have identical buoyant densities. If these nucleic acids should be free of unusual bases, it can be calculated<sup>8</sup> that this density corresponds to a guanine-cytosine content of 41 per cent.

Sea urchin eggs have been reported to contain 100 times more DNA in the cytoplasm than in the nucleus<sup>9</sup>. It is therefore noteworthy (Table 1) that the DNAs extracted by the phenol procedure from whole eggs and from isolated nuclei have the same buoyant density, thus indicating, by the criteria used, the identity of the nuclear and cytoplasmic DNA of *Arbacia punctulata*.

The buoyant density of the DNA isolated from diploid cells, although double-stranded, was consistently higher

Fig. 1. Buoyant densities of deoxyribonucleic acids isolated from the sperm, egg and somatic cells of the sea urchin *Arbacia punctulata*. The specimens from the sperm and diploid cells were isolated by a detergent procedure (ref. 3) whereas the DNA from the eggs was isolated by the hot phenol method (ref. 5). Portions of the specimens (2–5 µg) together with a reference sample (*Micrococcus lysodeikticus* DNA, 1.731 g/cm<sup>3</sup>) were placed in a caesium chloride solution of density 1.70 g/cm<sup>3</sup>. The samples were spun at 44,770 r.p.m. for 24 h and photographs were taken. The pictures were scanned with a Joyce-Loebel Mark III B densitometer and the densities of the specimens were calculated by comparison with the position of the reference DNA.

Fig. 2. Effect of heating and quick chilling on the buoyant density of DNA extracted from *Arbacia punctulata*. The DNA (30 µg/ml, 0.15 M NaCl in 0.015 M sodium citrate) was placed into a boiling water bath for 10 min and was then chilled by immersion in an ice-bath.

than the density of DNA derived from the gametes (Fig. 1 and Table 1). With the same reservations mentioned here, the buoyant density of this DNA can be calculated to correspond to a guanine-cytosine content of 43 per cent. An examination of Fig. 1 reveals that the buoyant density of DNA from somatic cells does not have a perfectly gaussian distribution, and this may account for the increased density. In this respect it is interesting that other investigations have also shown the DNA from adult somatic cells to be more heterogeneous with respect to density than is the nucleic acid isolated from haploid<sup>10</sup> or embryonic cells<sup>10,11</sup>.

The relationship of this increased density to development and cellular differentiation is now being investigated in this laboratory. In order to gain a better understanding of the mechanisms operative immediately after fertilization, sequence homologies between these nucleic acids will be looked for.

## MICROBIOLOGY

## Association of Bacterial L-Phase Organisms in Chronic Infections

THE pathogenicity, in the classic sense, of bacterial L-phase cells has yet to be conclusively demonstrated. The association of the L-phase of certain bacteria with diverse clinical states has been noted in the past, and this association is being reported more frequently as knowledge and interest in these forms have increased<sup>1-3</sup>. Such reported investigations lead to the assumption that host resistance mechanisms tend to create the L-phase of a bacterium. Experiments designed to determine the possible pathogenicity of the bacterial L-phase have usually ignored the host. It is not unreasonable to assume that the L-phase is the bacterial form most readily handled by normal host resistance mechanisms.

In regard to these assumptive possibilities, it was thought that chronic staphylococcal infections may be associated with L-phase bacteria. Patients were chosen for their history of chronic infection, usually associated with staphylococci. Blood samples, 10 ml., were drawn after the remission of clinical symptoms of disease brought about by antibiotic therapy. 5.0 ml. of each sample was injected immediately into 5.0 ml. double-strength L-phase minimal medium prepared according to the Mattman modification of the method of Medill and O'Kane<sup>10</sup>. The remaining 5.0 ml. was inoculated into 50 ml. 'sloppy' brain heart infusion medium (BHI plus 0.1 per cent agar). The inoculated L-phase medium was then incubated anaerobically until a change was obvious. Sometimes the only change was a slight haemolysis of the blood layer. Growth generally appeared by the end of the 5th-7th day of incubation. The 'sloppy' BHI was incubated aerobically for a minimum of two weeks.

When L-phase medium cultures were 5-7 days old, they were removed from the anaerobic chambers (95 per cent nitrogen; 5 per cent carbon dioxide) and two 0.5 ml. samples were inoculated into 4.5 ml. fresh medium. They were incubated either aerobically or anaerobically. Growth appeared in both tubes, but generally was greater in the tube incubated in the absence of air. At the time of maximal development (3-5 days) the organisms were again transferred to fresh medium and incubated aerobically. Adequate growth of the organism occurred in 3 days. These L-phase cells were then reverted to classic bacteria by daily transfers in BHI and on to 'Difco 110' medium slants. The cultures on the 'Difco 110' medium usually underwent a colour change from white to bright yellow during the successive transfers. The 'sloppy' BHI medium remained negative for any culture, even though the reverted L-phase cells were able to grow in this medium. Medium controls remained aseptic.

From a total of 11 patients selected for their history of recurring boils and staphylococcal problems, positive L-phase cells were obtained without the appearance of the classic bacterial forms. The L-phase cells all reverted to staphylococci after continued sub-culture.

As a control of the methodology, blood samples were taken from 22 apparently uninfected persons from the hospital staff. These blood samples were cultured in the routine process, and of these, 20 were negative. On re-testing samples of blood from the two whose blood had given positive cultures, no culture was obtained. The possibility of sub-acute infection in these two persons may be a reasonable explanation.

When large numbers of L-phase bacterial cells are injected into a healthy animal, no disease occurs and the L-phase cells are rapidly cleared. This may indicate merely that the animal is normal and therefore capable of efficiently handling the intruding cells. The classic bacterial growth form is not handled as well, if at all, and thus causes the symptomatic onset of disease. However, if the animal host resistance is interfered with by mucin

injection, then the L-phase cells survive, revert to the classic form and cause overt disease (unpublished results). Unfortunately, mucin is so non-specific in its interference with resistance that many factors only indirectly involved in host resistance are undoubtedly affected. The usual interpretation of this sequence of events is that the L-phase cells are non-pathogenic and are therefore not involved in the infectious process or the disease state. This interpretation may not be correct. We speculate that the inability to handle L-phase bacteria may be related to an incomplete host resistance system caused by stress or inherited deficiencies. The consequence of survival of the L-phase in tissues not amenable to therapy would, therefore, be chronic disease. During therapy no overt disease state may exist. If therapy should be discontinued before the host resistance system is functioning efficiently, the surviving L-cells may slowly revert to classic growth forms and eventually give rise to overt disease. It would be expected that during therapy, however, the host defence mechanisms would become more active or that the physical or biochemical stress would have disappeared. This would allow complete recovery. Complete recovery may be primarily dependent on the reacquisition of host resistance factors rather than on the course of chemotherapeutic treatment.

A more extensive investigation of chronic staphylococcal L-phase infection should be initiated. Other chronic disease states should be examined during various phases of treatment and non-treatment for possible L-phase association. Rheumatic fever comes to mind as a most logical chronic disease that could be associated with streptococcal L-phase survival, perhaps localized in heart valve tissue.

The association of L-phase cells in cases of chronic infections of humans which have been treated with antibiotics requires greater consideration than has been outlined in this report. The possible involvement of the bacterial L-phase in this type of infection should no longer be ignored.

## CYTOLOGY

## A New Basic Chromosome Number in the Family Fagaceae

CHROMOSOME numbers have been determined previously for some 58 species in the family Fagaceae, covering the three genera of the northern temperate zone, *Quercus*, *Castanea* and *Fagus*<sup>1-3</sup>. These determinations are uniformly  $2n = 24$ , the Fagaceae resembling many other families of woody angiosperms in this stability of chro-

Fig. 1. Diakinesis in *N. solandri* var. *cliffortioides*, with 13 bivalents ( $\times 1,500$ )

Fig. 2. Anaphase I in *N. menziesii*, 13 chromosomes moving to each pole ( $\times 1,500$ )

mosome number. The southern beech genus, *Nothofagus*, with some 20 species distributed in temperate South America, New Zealand and Australia and extending up into New Guinea and New Caledonia, was at one time included in *Fagus*, and it is more closely allied in features of floral and pollen morphology to *Fagus* than to any of the other genera in the family<sup>4-6</sup>. The four New Zealand species are all endemic and are the principal evergreen hardwoods in much of the indigenous forest. They include representatives of two of the sections into which the genus is divided: in the *fusca* section, *N. fusca*, *N. truncata* and *N. solandri*, all of which hybridize freely in the wild, and in the *menziesii* section, *N. menziesii*, which is not known to cross with any of the other species.

Chromosome numbers have been determined from meiotic divisions in pollen mother cells for the three species growing in Otago: *N. menziesii* (silver beech), *N. fusca* (red beech) and *N. solandri* var. *cliffortioides* (mountain beech)<sup>7</sup>. Meiosis occurs very early in the spring and is completed very rapidly indeed in any one locality. Thirteen bivalents are uniformly present in diakinesis and metaphase I cells (Fig. 1), and cells at anaphase I show 13 chromosomes moving to each pole (Fig. 2). The chromosomes are small (as is usually the case in trees), with median to sub-median centromeres. *N. menziesii* has a significantly lower mean chiasma frequency per cell than the two species in the section *fusca*. Meiosis is normal and leads to the formation of regular tetrads.

This discovery that *Nothofagus* has a haploid number of 13, in contrast to that of 12 in all other members of the family for which information is available, vindicates its generic status. One might even ask whether exclusion from the family Fagaceae is warranted. However, the morphological resemblance to *Fagus* is strong. Both *Fagus* and *Nothofagus* have fossil records going back to the Cretaceous<sup>8</sup>. The basic number of  $x = 13$  could have been derived from the  $x = 12$  condition by the same mechanism, involving unequal translocation, as was postulated by Darlington for *Fritillaria*<sup>8</sup>. *Nothofagus* would thus be a specialized offshoot from a *Fagus*-like ancestor arising early in the evolution of the family. Alternatively,  $x = 13$  could represent an intermediate stage in the origin through stepwise reduction (as in *Crepis*) of  $x = 12$  from  $x = 14$  which is the predominant number in the other two families in the order Fagales, Betulaceae and Corylaceae<sup>1</sup>. *Nothofagus* would then be a conservative ancestral form. If the occurrence of *Nothofagus* pollen in the Eocene of the Isle of Wight<sup>10</sup> is confirmed this will become the more probable alternative. But information on the chromosome numbers of the Australian and South American species of *Nothofagus*

and also of the tropical genera in the family, as yet quite unknown cytologically, may help in deciding this question.

### Ultrastructural Continuity between Active and Repressed Chromatin

DURING metaphase and anaphase of cell mitosis, mammalian chromosomes are highly condensed, individually distinct, and relatively inert in ribonucleic acid (RNA) synthesis<sup>1-5</sup>. By late telophase, the chromosomes become less condensed, appear less distinct from each other, and begin the synthesis of RNA<sup>1-5</sup>. By early interphase, all distinction between individual chromosomes is lost, and the chromosomal substance is visible either as condensed masses (chromocentres, heterochromatin) of repressed chromatin<sup>6,7</sup>, or as extended microfibrils (euchromatin) of chromatin actively synthesizing RNA<sup>6,7</sup>.

The chromosomal karyotype and gene-linkage pattern within a cell normally remain constant from one mitosis to the next<sup>8</sup>, indicating that the structural integrity of each chromosome is maintained throughout interphase<sup>9</sup>. This implies that the repressed and active portions of a chromosome in favourable material might display structural continuity during cell interphase<sup>10</sup>.

In the course of the isolation of repressed and active chromatin from interphase calf thymus lymphocytes<sup>6</sup>, a stage is reached in which the nuclei swell to twice their normal size, offering a favourable material for the examination of the structural relations between the active chromatin microfibrils and the repressed chromatin masses. Such swollen nuclei were prepared and examined by electron microscopy as described previously<sup>6</sup>.

The condensed masses of repressed chromatin tend to be arrayed at the periphery of the swollen nucleus (Fig.

Fig. 1. Swollen nuclei displaying condensed masses of repressed chromatin and extended microfilaments of active chromatin. ( $\times 11,250$ )

Fig. 2. Detail of swollen nucleus displaying the structural continuity of active microfilaments with repressed masses of chromatin. ( $\times 30,000$ )

1), while the extended microfilaments of active chromatin are dispersed between the masses within the interior of the nucleus (Fig. 1). Higher magnifications reveal the active chromatin microfilaments to be of 100 Å diameter (Fig. 2), and these microfilaments can be traced for up to 1.0  $\mu$  of their length (Fig. 2). These extended microfilaments of active chromatin are seen to be structurally continuous with a dense reticulum of fibres within the condensed masses of repressed chromatin (Fig. 2). The zone of transition between the extended microfilaments and the condensed masses is sharp, occurring within less than 100 Å of the length of the microfilaments.

The molecular basis of these structural transitions may lie in the excess of such polyanions as phosphoproteins, RNA, and phospholipids recently found within extended active chromatin as compared to condensed repressed chromatin<sup>11</sup>. These chromatin polyanions can function as de-repressors of RNA synthesis within repressed chromatin by antagonizing the electrostatic interaction between the deoxyribonucleic acid (DNA) and the polycationic repressor histones of repressed chromatin<sup>11</sup>.

I thank Drs. A. E. Mirsky, V. G. Allfrey, V. C. Littau, and T. A. Langan for their advice. This work was supported by a research career development award from the U.S. Public Health Service.

## MATHEMATICS

### Unified Relativity and Quantum Theory

A MATHEMATICAL model has been constructed which reconciles the series of relativity, electro-magnetism and quantum mechanics. It is a deterministic theory, and avoids the rather mystical appeal to fundamental indeterminism which is so prevalent in interpretations of quantum effects.

The 6-vector concomitant of a real basic spinor distribution, which satisfies the fundamental differential equation  $\text{curl } W = 0$ , represents precisely the electromagnetic field of light waves. The purpose behind this investigation was to express the general electromagnetic field as a concomitant of a spinor distribution. The following steps become necessary. First, the spinors are made complex. It is then necessary to interpret the phase as a periodic fifth dimension, as in Kaluza's unified theory of gravitation and electromagnetism, and to assume a topological singularity, which is later identified with spin. The Kaluza theory is then incorporated in the model, the curvature invariants being determined by the concomitants of the spinor.

To extend the differential equation  $\text{curl } W = 0$  to 5 dimensions, the complex nature of the spinors must be reintroduced, since spinors in 5-space of signature 3 must be complex. The differential equation led to wave packets without singularities, which can be interpreted as particles. Dirac's relativistic electron equations follow, the 'negative energy' terms corresponding to waves propagated in the reverse direction round the fifth dimensional cylinder. Stationary orbits and the energy frequency rules for spectra follow.

The final model consists of a 5-dimensional space-time with a distribution of spinors which satisfy the fundamental differential equation. The curvature components of the space-time are determined by the concomitants of the spinors. This model would seem to yield all the principal quantum effects and equations, which fit in with the gravitational and electromagnetic effects via the Kaluza model.

The interaction of two particles corresponding to spinor waves  $W = W_1 + W_2$  is through the effects on the geometry which depend on concomitants of the form:

$$\tilde{W}\psi W = \tilde{W}_1\psi W_1 + \tilde{W}_2\psi W_1 + \tilde{W}_1\psi W_2 + \tilde{W}_2\psi W_2$$

This introduces naturally the interaction terms of the form  $W_1\psi W_2$  so frequently used in quantum mechanics.

A paper on space-time distributions of spinors has been submitted to the Royal Society for publication.

D. E. LITTLEWOOD

Department of Mathematics,  
University College of North Wales, Bangor.

## FORTHCOMING EVENTS

(Meetings marked with an asterisk are open to the public)

## Monday, March 29

INSTITUTION OF ELECTRICAL ENGINEERS, SCIENCE AND GENERAL DIVISION (at Savoy Place, London, W.C.2), at 10 a.m., 2.30 p.m. and 5.30 p.m.—Colloquium on "Earth Loop Impedance Testing".

INSTITUTION OF ELECTRICAL ENGINEERS, ELECTRONICS DIVISION (at Savoy Place, London, W.C.2), at 5.30 p.m.—Mr. P. Knight, Mr. R. E. Davies and Dr. R. G. Manton: "Vertical Radiation Patterns of h.f. Curtain Arrays on Plateau Sites".

PLASTICS INSTITUTE, LONDON SECTION REINFORCED PLASTICS SUB-GROUP (at the Eccleston Hotel, London, S.W.1), at 7.30 p.m.—Mr. J. W. Davidson: "Plastics in Building".

ROYAL GEOGRAPHICAL SOCIETY (at 1 Kensington Gore, London, S.W.7), at 8.15 p.m.—Mr. Michael P. Ward: "In Unknown Bhutan".

## Tuesday, March 30

INSTITUTION OF CIVIL ENGINEERS (at Great George Street, Westminster, London, S.W.1), at 5.30 p.m.—Mr. E. H. Vick, Mr. J. G. Paterson, Mr. L. B. Escrib, Mr. V. F. Cornish and Mr. W. C. Andrews: "The Southern Outfall Works of the London County Council".

ROYAL INSTITUTION (at 21 Albemarle Street, London, W.1), at 5.30 p.m.—Prof. R. J. Harrison: "Characteristics of Man". (Afternoon lecture for Sixth Form Boys and Girls in Schools from London and the Home Counties. To be repeated on March 31, April 6 and 7.)

## Tuesday, March 30—Wednesday, March 31

SOCIETY OF CHEMICAL INDUSTRY, PESTICIDES GROUP (joint meeting with the Colloid and Surface Chemistry Group (at the School of Pharmacy, Brunswick Square, London, W.C.1)—Symposium on "Formulation of Pesticides".

## Wednesday, March 31

SYSTEMATICS ASSOCIATION (in the Lecture Hall of the British Museum (Natural History), London, S.W.7), 10.15 a.m.—Demonstration Meeting on "Methods in Taxonomy".

INSTITUTION OF MECHANICAL ENGINEERS, INTERNAL COMBUSTION ENGINES GROUP (at 1 Birdcage Walk, Westminster, London, S.W.1), at 6 p.m.—Discussion on "Methods of Rating Diesel Engines in Mass Production".

ROYAL AERONAUTICAL SOCIETY (at 4 Hamilton Place, London, W.1), at 6 p.m.—Discussion Meeting on "The Difficulties and Advantages of Super-sonic Civil Transport" opened by Dr. A. E. Russell and Mr. B. S. Shenstone.

ROYAL SOCIETY OF ARTS (at John Adam Street, Adelphi, London, W.C.2), at 6 p.m.—Sir Willis Jackson, F.R.S.: "New Materials in Engineering" (Trueman Wood Lecture).

INSTITUTION OF ELECTRICAL ENGINEERS, LONDON GRADUATE AND STUDENT SECTION (Annual Joint Meeting with the Graduate and Students Sections of the Institutions of Civil and Mechanical Engineers, at the Institution of Electrical Engineers, Savoy Place, London, W.C.2), at 6.30 p.m.—Mr. B. Z. De Ferranti: "Computers".

SOCIETY FOR ANALYTICAL CHEMISTRY (at the Chemical Society, Burlington House, Piccadilly, London, W.1), at 7 p.m.—Meeting on "Food Analysis".

## Thursday, April 1

ROYAL SOCIETY (at Burlington House, Piccadilly, London, W.1), at 4.30 p.m.—Dr. R. R. Race, F.R.S.: "Contributions of Blood Groups to Human Genetics". (Review Lecture.)

INSTITUTION OF ELECTRICAL ENGINEERS (at Savoy Place, London, W.C.2), at 5.30 p.m.—Mr. B. P. Miller: "Ranger 8 Spacecraft, with special reference to Moon Shot Camera Systems".

INSTITUTE OF REFRIGERATION (at the National College for Heating, Ventilating, Refrigeration and Fan Engineering, Southwark Bridge Road, London, S.E.1), at 6 p.m.—Mr. A. K. Alcock: "Trends in Hermetic Unit Design and Applications".

INSTITUTION OF MECHANICAL ENGINEERS, AUTOMATIC CONTROL GROUP (at 1 Birdcage Walk, Westminster, London, S.W.1), at 6 p.m.—Discussion on "Economics of Automatic Control in Shipping".

## Thursday, April 1—Friday, April 2

BIOCHEMICAL SOCIETY (at University College, Gower Street, London, W.C.1)—Annual General Meeting. Thursday, April 1—Symposium on "The Biochemistry of Insects", followed by Prof. A. Szent-Györgyi: "Growth and Cellular Organization" (Fifth Hopkins Memorial Lecture). Friday, April 2—Scientific Papers followed by the Annual General Business Meeting.

CLAY MINERALS GROUP OF THE MINERALOGICAL SOCIETY (in the Geology Department, The University, Liverpool)—Spring Meeting: "Clay Minerals in Chemical Industry".

## Friday, April 2

INSTITUTION OF MECHANICAL ENGINEERS (at 1 Birdcage Walk, Westminster, London, S.W.1), at 10.30 a.m. and 2.30 p.m.—Mr. H. Mundy and Mr. P. Spear: "Motor Racing—a Challenge to the Engineer" (Leonardo da Vinci Lecture).

BRITISH MYCOLOGICAL SOCIETY, PLANT PATHOLOGY COMMITTEE (in the Large Physics Lecture Theatre, Imperial College, Prince Consort Road, London, S.W.7), at 10.45 a.m.—Symposium on "Plant Disease Control by Antibiotics, Cultural, and Other Methods".

INSTITUTION OF ELECTRICAL ENGINEERS, ELECTRONICS DIVISION (at Savoy Place, London, W.C.2), at 5.30 p.m.—Mr. C. W. Earp: "Features of a New Doppler VOR Beacon".

INSTITUTION OF ELECTRICAL ENGINEERS, POWER DIVISION (at Savoy Place, London, W.C.2), at 5.30 p.m.—Discussion on "Testing of Power Semiconductor Devices and Standardization", opened by Mr. W. D. Sinclair.

## Saturday, April 3

BRITISH MYCOLOGICAL SOCIETY (at Imperial College, London, S.W.7), from 11 a.m. to 5 p.m.—Conversazione.

## Monday, April 5

INSTITUTION OF ELECTRICAL ENGINEERS, ELECTRONICS DIVISION (joint meeting with the I.E.R.E. Computer Group, at Savoy Place, London, W.C.2), at 2.30 p.m.—Colloquium on "The Design of Real Computer Systems".

SOCIETY OF CHEMICAL INDUSTRY, LONDON SECTION (at 14 Belgrave Square, London, S.W.1), at 6.30 p.m.—Mr. Robert T. Clough: "The Old Lead Smelting Mills of the Yorkshire Dales".

## Monday, April 5—Wednesday, April 7

BRITISH NATIONAL SECTION OF THE INTERNATIONAL ASSOCIATION FOR EARTHQUAKE ENGINEERING (at Imperial College of Science and Technology, London, S.W.7)—Symposium on "Vibration in Civil Engineering".

## APPOINTMENTS VACANT

APPLICATIONS are invited for the following appointments on or before the dates mentioned:

LECTURER (either a theoretical reactor physicist with experience in modern computational techniques or a candidate well qualified in the fields of fluid dynamics and heat transfer) IN THE DEPARTMENT OF NUCLEAR ENGINEERING—The Registrar, Queen Mary College (University of London), Mile End Road, London, E.1 (April 1).

LECTURER/ASSISTANT LECTURER (preferably with experience in magnetic resonance or gas discharges or mechanical properties of materials or astronomy) IN THE DEPARTMENT OF PHYSICS—The Registrar, The University, Keele, Staffordshire (April 2).

ASSISTANT LECTURER or UNIVERSITY DEMONSTRATOR IN THE DEPARTMENT OF ZOOLOGY—The Secretary, University of Edinburgh, The Old College, South Bridge, Edinburgh, 8 (April 3).

LECTURER (science graduate) IN THE DEPARTMENT OF BACTERIOLOGY—The Registrar, The University, Liverpool, quoting Ref. CV/10/N (April 3).

LECTURER (with a good honours degree or equivalent and appropriate experience in teaching, research or industry) IN ZOOLOGY IN THE DEPARTMENT OF BIOLOGY—The Academic Registrar, Brunel College, Woodlands Avenue, London, W.3 (April 3).

HEAD (with high academic qualifications and research or industrial experience in biology or related fields of study, and preferably some administrative experience) OF THE DEPARTMENT OF BIOLOGICAL SCIENCES—The Registrar, Portsmouth College of Technology, Hampshire Terrace, Portsmouth (April 5).

LECTURER IN PURE MATHEMATICS—The Secretary, Birkbeck College (University of London), Malet Street, London, W.C.1 (April 5).

PRINCIPAL LECTURER (with high academic qualifications and preferably some industrial or research experience) IN MATHEMATICS—The Principal, Lanchester College of Technology, Coventry (April 5).

RESEARCH STUDENTS (2) IN THE DEPARTMENT OF ZOOLOGY, to pursue research on various aspects of nutrition in the Platyhelminthes, Rhynchocoela and Nematoda, as part of a research project financed by the United States Public Health Service—Dr. J. B. Jennings, Department of Zoology, The University, Leeds, 2 (April 5).

RESEARCH ASSISTANT IN THE SUB-DEPARTMENT OF COMPUTATION, DEPARTMENT OF MATHEMATICS—The Registrar, The University, Hull (April 9).

EXPERIMENTAL OFFICER (with a university degree or its equivalent) IN THE DEPARTMENT OF ZOOLOGY for technical duties in connexion with research in the field of comparative endocrinology—The Registrar, The University, Sheffield (April 10).

RESEARCH ASSISTANT (graduate with research experience) IN THE DEPARTMENT OF PHYSICS to work on the application of electron microscopy to the study of ferromagnetic domains—The Registrar, The University, Sheffield (April 10).

SENIOR LECTURER and a LECTURER (graduate of medicine or science) IN THE DEPARTMENT OF PHYSIOLOGY—The Assistant Registrar, The Medical School (University of Birmingham), Birmingham, 15 (April 10).

LECTURER IN PHYSICS—The Secretary, The Queen's University, Belfast, Northern Ireland (April 11).

ASSISTANT LECTURER (with a special interest in social and economic geography) IN GEOGRAPHY—The Registrar, The University, Sheffield (April 12).

LECTURER IN PHYSICAL CHEMISTRY—The Very Reverend the Dean, Christ Church, Oxford (April 12).

READER IN HISTOLOGY at Guy's Hospital Medical School—The Academic Registrar, University of London, Senate House, London, W.C.1 (April 12).

ASSISTANT (with an honours degree in an appropriate science or a post-graduate qualification in agricultural engineering or farm mechanization) IN RESEARCH IN AGRICULTURAL ENGINEERING—The Secretary, School of Agriculture, University of Cambridge, Cambridge (April 14).

CHAIR OF COMPUTER SCIENCE—The Secretary, The Queen's University, Belfast, Northern Ireland (April 14).

LECTURER/ASSISTANT LECTURER (with at least a good honours degree with suitable teaching and research experience, and special qualifications in one or more of the following fields: analytical chemistry, chemical technology, inorganic chemistry or physical chemistry) IN THE DEPARTMENT OF CHEMISTRY, University of Malaya—The Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (Kuala Lumpur and London, April 15).

READER IN THEORETICAL PHYSICS, and a LECTURER IN THEORETICAL PHYSICS (preferably interested in physics of the solid state)—The Secretary, Chelsea College of Science and Technology, Manresa Road, London, S.W.3 (April 15).

CHAIR OF INORGANIC CHEMISTRY—The Secretary, The University, Aberdeen (April 17).

CHAIR OF PHYSICAL GEOGRAPHY—The Secretary, The University, Aberdeen (April 17).

SENIOR LECTURER, a LECTURER and an ASSISTANT LECTURER IN THE DEPARTMENT OF PSYCHOLOGY—The Secretary, The University, Aberdeen (April 17).

LECTURER or ASSISTANT LECTURER (with an interest and preferably research experience in plant virology) IN THE DEPARTMENT OF AGRICULTURAL BOTANY—The Registrar, University College of Wales, Aberystwyth (April 21).

SENIOR LECTURER and a LECTURER (preferably with experience in the fields of entomology and fresh-water biology) IN THE DEPARTMENT OF ZOOLOGY, University of Ghana—The Assistant Registrar, Higher Education

Section, Ghana High Commission, 15 Gordon Square, London, W.C.1; or The Registrar, University of Ghana, P.O. Box No. 25, Legon, Accra, Ghana (Ghana, April 22).

LECTURER or ASSISTANT LECTURER (preferably with an interest in the teaching of Greek philosophy) in PHILOSOPHY—The Secretary, The Queen's University, Belfast, Northern Ireland (April 25).

ASSISTANTS IN CHEMISTRY—The Secretary of the University Court, The University, Glasgow (April 30).

CHAIR OF ZOOLOGY—The Registrar, University of Newcastle upon Tyne, 6 Kensington Terrace, Newcastle upon Tyne, 2 (April 30).

LECTURER (with a higher degree in botany, some experience in teaching and research, and preferably an interest in ecology, anatomy or systematics) in BOTANY at the University College of Townsville (University of Queensland), Australia—Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (London and Brisbane, April 30).

LECTURER (with a special interest and research experience in electrochemistry) in PHYSICAL CHEMISTRY—The Secretary of the University Court, The University, Glasgow (April 30).

LECTURER (with either a medical degree or a degree in pharmacology) in PHARMACOLOGY at the University of Cape Town—The Secretary-General, Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1; and The Registrar, University of Cape Town, Private Bag, Rondebosch, Cape Town, South Africa (April 30).

SOIL SURVEYORS (with a good honours degree) FOR THE SOIL SURVEY OF ENGLAND AND WALES—The Secretary, Rothamsted Experimental Station, Harpenden, Hertfordshire (April 30).

TUTORIAL FELLOW (preferably under 40 years of age) in ENGINEERING SCIENCE at University College, Oxford, which will be held in conjunction with a post in the Department of Engineering Science—The Senior Tutor, University College, Oxford (April 30).

UNIVERSITY DEMONSTRATOR IN ORGANIC CHEMISTRY—Dr. P. Maitland, University Chemical Laboratory, Lensfield Road, Cambridge (April 30).

LECTURER (preferably with research interests in the field of invertebrate physiology, particularly insect physiology) in ZOOLOGY at the Australian National University—The Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (Australia and London, May 3).

SENIOR LECTURER/LECTURER IN MATHEMATICAL STATISTICS IN THE FACULTY OF ECONOMICS, Australian National University—The Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (Australia and London, May 3).

SENIOR LECTURER or LECTURER IN PHYSICAL or THEORETICAL CHEMISTRY at the Australian National University—The Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (Australia and London, May 3).

SENIOR LECTURERS or LECTURERS (2) IN PURE MATHEMATICS, at the Australian National University—The Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (Australia and London, May 3).

CHAIR IN NUCLEAR PHYSICS at the University of Auckland, New Zealand—The Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (New Zealand and London, May 7).

LECTURER (Grade II) in ENTOMOLOGY WITHIN THE DEPARTMENT OF ZOOLOGY—The Registrar, University Senate House, Tyndall Avenue, Bristol, 2 (May 31).

ASSISTANT or ASSOCIATE PROFESSOR (with a Ph.D. in soil science from a recognized university, and preferably a minor in physical chemistry) of SOIL SCIENCE—D. A. Rennie, Head, Department of Soil Science, University of Saskatchewan, Saskatoon, Saskatchewan, Canada.

HORTICULTURIST (national of the United Kingdom or the Republic of Ireland, with a degree in horticulture, agriculture or natural science, plus experience in tropical countries with fruit crops) in Bolivia, to initiate experiments with tropical fruit crops, sub-tropical crops and temperate crops under sub-tropical conditions, and to organize extension work and train local staff—Appointments Officer, Room 301, Ministry of Overseas Development, Eland House, Stag Place, London, S.W.1, quoting Ref. RC 213/22/04.

HOSPITAL PHYSICIST (with a science degree in physics or equivalent qualification) in the RADIOTHERAPY CENTRE, Canterbury, for work on medical treatment with radio-isotopes, cobalt beam and other forms of ionizing radiation—The Hospital Secretary, Kent and Canterbury Hospital, Canterbury, Kent.

MASTER (graduate) to teach physics to advanced level—The Headmaster, Allyn's School, London, S.E.22.

MANAGER (with a first degree, or its equivalent, in mathematics and considerable experience in the operation of computers in, and for, industry) of THE COMPUTER CENTRE, to take charge of the operation of the existing IBM 1620 computer, and of additional computers that may be installed in the Centre—The Registrar, Loughborough College of Technology, Loughborough, Leicestershire.

MICRO-ANALYST in the CHEMISTRY DEPARTMENT to conduct routine analysis of organic compounds—The Secretary, Department of Chemistry, University of British Columbia, Vancouver, 8, Canada.

PRINCIPAL LECTURER IN MATHEMATICS to teach one branch of mathematics up to the standard of the B.Sc. (Special Mathematics) degree—Clerk to the Governing Body, Northern Polytechnic, Holloway, London, N.7.

PRINCIPAL/SENIOR RESEARCH OFFICERS (nationals of the United Kingdom or the Republic of Ireland, with a good honours degree in botany or chemistry with appropriate postgraduate training and experience) in Uganda, to be responsible for detailed supervision of research work which may involve taking full charge of a main research station—The Appointments Officer, Room 301, Ministry of Overseas Development, Eland House, Stag Place, London, S.W.1, quoting Ref. RC 213/183/05.

RESEARCH FELLOWS in the CHEMISTRY DEPARTMENT, for work under Prof. R. M. Barrer, on (1) non-stoichiometric inclusion and clathration complexes, and (2) high pressure adsorption of gases by porous crystals and molecular sieves—Prof. R. M. Barrer, F.R.S., Chemistry Department, Imperial College, London, S.W.7.

Bonds, Part 2 (Covalent Bond). 29 frames+booklet. 5: Chemical Bond Part 3 (Conclusion). 21 frames+booklet. (Surbiton: Marian Bay, Villiers Avenue, 1964.)

British Museum (Natural History). The John Murray Expedition, 1933-4 Scientific Reports, Vol. 10. No. 8: Crustacea: Chirostyliidae (Galatheidæ) By Dr. Nasima M. Tirmizi. Pp. 385-415. (London: British Museum (Natural History), 1964.) 15s.
